COMPUTATIONAL METHODS FOR STOCHASTIC RELATIONS AND MARKOVIAN COUPLINGS

Lasse Leskelä
COMPUTATIONAL METHODS FOR STOCHASTIC RELATIONS AND MARKOVIAN COUPLINGS

Lasse Leskelä

**Abstract:** Order-preserving couplings are elegant tools for obtaining robust estimates of the time-dependent and stationary distributions of Markov processes that are too complex to be analyzed exactly. The starting point of this paper is to study stochastic relations, which may be viewed as natural generalizations of stochastic orders. This generalization is motivated by the observation that for the stochastic ordering of two Markov processes, it suffices that the generators of the processes preserve some, not necessarily reflexive or transitive, subrelation of the order relation. The main contributions of the paper are an algorithmic characterization of stochastic relations between finite spaces, and a truncation approach for comparing infinite-state Markov processes. The methods are illustrated with applications to loss networks and parallel queues.

1 Introduction

Comparison techniques based on stochastic orders [12, 13, 14] are key to obtaining upper and lower bounds for complicated random variables and processes in terms of simpler random elements. Consider for example two ergodic discrete-time Markov processes $X$ and $Y$ with stationary distributions $\mu_X$ and $\mu_Y$, taking values in a common ordered state space, and denote by $\leq_{st}$ the corresponding stochastic order. Then the upper bound

$$\mu_X \leq_{st} \mu_Y$$  \hspace{1cm} (1)

can be established [6] without explicit knowledge of $\mu_X$ by verifying that the corresponding transition probability kernels $P_X$ and $P_Y$ satisfy

$$x \leq y \implies P_X(x, \cdot) \leq_{st} P_Y(y, \cdot).$$  \hspace{1cm} (2)

Analogous conditions for continuous-time Markov processes on countable spaces have been derived by Whitt [15] and Massey [11], and later extended to more general jump processes by Brandt and Last [2].

Less stringent sufficient conditions for obtaining (1) have recently been found using a new theory stochastic relations [9]. Two random variables are stochastically related, denoted by $X \sim_{st} Y$, if there exists a coupling $(\hat{X}, \hat{Y})$ of $X$ and $Y$ such that $\hat{X} \sim \hat{Y}$ almost surely, where $\sim$ denotes some relation between the state spaces of $X$ and $Y$. The main motivation for this definition is that (2) is by no means necessary for (1); a less stringent sufficient condition is that

$$x \sim y \implies P_X(x, \cdot) \sim_{st} P_Y(y, \cdot)$$  \hspace{1cm} (3)

for some, not necessarily symmetric or transitive, nontrivial subrelation of the underlying order relation. Another advantage of the generalized definition is that $X$ and $Y$ are no longer required to take values in the same state space, leading to greater flexibility in the search for bounding random elements.

For example, to study whether $f(X) \leq_{st} g(Y)$ for some given real functions $f$ and $g$ defined on the state spaces of $X$ and $Y$, we may define a relation $x \sim y$ by the condition $f(x) \leq g(y)$ [3].

The rest of the paper is outlined as follows. After recalling the basic definitions, Section 2 presents a numerical algorithm for verifying stochastic relations between finite spaces, together with an analysis of computational complexity. Section 3 recalls how a recursive subrelation algorithm may be used to find Markovian couplings preserving a given relation. In Section 4, a new truncation approach is presented that allows to precisely compute truncated outcomes of the subrelation algorithm for infinite-state Markov processes with locally bounded jumps. Section 5 discusses applications to loss networks and parallel queues, and Section 6 concludes the paper.
2 Stochastic relations

2.1 General definitions

We shall here recall the definitions of stochastic relations between countable spaces. Probability measures $\mu$ on a countable state space $S$ shall be viewed as a probability vectors via identifying $\mu(x) = \mu(\{x\})$. For a treatment on more general spaces, see [9].

A relation between $S_1$ and $S_2$ is subset of $S_1 \times S_2$. Given a nontrivial $(R \neq \emptyset)$ relation $R$ between $S_1$ and $S_2$, we write

$$x \sim y,$$

if $(x, y) \in R$. The relation $R$ may equivalently be viewed as a matrix so that $R(x, y) = 1$ if $x \sim y$ and $R(x, y) = 0$ otherwise. A coupling of probability vectors $\mu$ on $S_1$ and $\nu$ on $S_2$ is a probability vector $\lambda$ on $S_1 \times S_2$ with marginals $\mu$ and $\nu$, that is,

$$\sum_{y \in S_2} \lambda(x, y) = \mu(x) \quad \text{for all } x \in S_1,$$

$$\sum_{x \in S_1} \lambda(x, y) = \nu(y) \quad \text{for all } y \in S_2.$$

For probability vectors $\mu$ on $S_1$ and $\nu$ on $S_2$ we denote

$$\mu \sim_{st} \nu,$$

and say that $\mu$ is stochastically related to $\nu$, if there exists a coupling $\lambda$ of $\mu$ and $\nu$ such that

$$\sum_{(x, y) \in R} \mu(x, y) = 1.$$

The relation $R_{st} = \{(\mu, \nu) : \mu \sim_{st} \nu\}$ is called the stochastic relation generated by $R$. Observe that two Dirac masses satisfy $\delta_x \sim_{st} \delta_y$ if and only if $x \sim y$. In this way the stochastic relation $R_{st}$ may be regarded as a natural randomization of the underlying relation $R$.

The following result in [9], which is rephrased here for ease of reference, provides an analytical method to check whether a pair of probability measures are stochastically related.

**Theorem 1.** [9] Two probability vectors $\mu$ and $\nu$ are stochastically related with respect to $R$ if and only if

$$\sum_{x \in U} \mu(x) \leq \sum_{y \in S_2} \left( \max_{x \in U} R(x, y) \right) \nu(y) \quad (4)$$

for all finite $U \subset S_1$, or equivalently, if and only if

$$\sum_{y \in V} \nu(y) \leq \sum_{x \in S_1} \left( \max_{y \in V} R(x, y) \right) \mu(x) \quad (5)$$

for all finite $V \subset S_2$. 

4
A random variable $X$ is \textit{stochastically related} to a random variable $Y$, denoted by $X \sim_{st} Y$, if the distribution of $X$ is stochastically related to the distribution of $Y$. Observe that $X$ and $Y$ do not need to be defined on the same probability space. Recall that a coupling of random variables $X$ and $Y$ is a bivariate random variable whose distribution couples the distributions of $X$ and $Y$. Hence $X \sim_{st} Y$ if and only if there exists a coupling $(\hat{X}, \hat{Y})$ of $X$ and $Y$ such that $\hat{X} \sim \hat{Y}$ almost surely.

**Example 1.** If $\leq$ is an order (reflexive and transitive) relation on a space $S$, then the corresponding stochastic relation $\leq_{st}$ is called a stochastic order. Using Strassen’s classical theorem [12], we see that $X \sim_{st} Y$ if and only if $E f(X) \leq E f(Y)$ for all positive increasing functions $f$ on $S$.

### 2.2 Stochastic relations between finite spaces

Let $R$ be a relation between finite spaces $S_1$ and $S_2$, and denote by $R_{st}$ the corresponding stochastic relation. Then Theorem 1 may be used to determine whether $\mu \sim_{st} \nu$. However, this requires to check the inequality (4) for all subsets of $S_1$, which is computationally infeasible unless the spaces are small. The following result shows that less checks may be sufficient. We shall denote the support of a probability vector $\mu$ by $U_\mu = \{ x : \mu(x) > 0 \}$. Moreover, we denote by $F(U, \mathbb{Z}_2)$ the set of vectors with components in $\{0, 1\}$ indexed by elements of $U$, which may also be identified as the set of all subsets of $U$.

**Theorem 2.** Two probability vectors $\mu$ and $\nu$ with supports $U_\mu$ and $U_\nu$ are stochastically related with respect to $R$ if and only if

$$\sum_{x \in U_\mu} f(x) \mu(x) \leq \sum_{y \in U_\nu} \max_{x \in U_\mu} \left[ f(x) R(x, y) \right] \nu(y)$$

for all $f \in F(U_\mu, \mathbb{Z}_2)$, or equivalently, if and only if

$$\sum_{y \in U_\nu} g(y) \nu(y) \leq \sum_{x \in U_\mu} \max_{y \in U_\nu} \left[ R(x, y) g(y) \right] \mu(x)$$

for all $g \in F(U_\nu, \mathbb{Z}_2)$.

**Proof.** In light of Theorem 1, it suffices to show the equivalence of (4) and (6), and the equivalence of (5) and (7). Observe that (4) directly implies (6), because the members of $F(U_\mu, \mathbb{Z}_2)$ may be identified with the indicator functions of subsets of $U_\mu$. To prove the converse, assume that (6) holds, and let
Let $U$ be an arbitrary subset of $S_1$. Define $f(x) = 1(x \in U \cap U_\mu)$. Then
\[
\sum_{x \in U} \mu(x) = \sum_{x \in U_\mu} f(x) \mu(x) \\
\leq \sum_{x \in U_\mu} \max_{y \in U_\nu} [f(x) R(x, y)] \nu(y) \\
= \sum_{y \in S_2} \left( \max_{x \in U_\mu \cap U} R(x, y) \right) \nu(y) \\
\leq \sum_{y \in S_2} \left( \max_{x \in U} R(x, y) \right) \nu(y).
\]
Hence (4) holds. Proving the equivalence of (5) and (7) is completely analogous.

Algorithm 1

Determining whether $\mu \sim_{st} \nu$.

1. $U_\mu \leftarrow \{ x \in S_1 : \mu(x) > 0 \}$
2. $U_\nu \leftarrow \{ y \in S_2 : \nu(y) > 0 \}$
3. if $#U_\mu > #U_\nu$ then
   flip $\mu \leftrightarrow \nu$, $U_\mu \leftrightarrow U_\nu$, $S_1 \leftrightarrow S_2$
4. end if
5. $b \leftarrow$ true
6. for $i = 1, \ldots, 2#U_\mu$ do
   7. $f \leftarrow i$-th vector in $F(U_\mu, Z_2)$
   8. $v_l \leftarrow \sum_{x \in U_\mu} f(x) \mu(x)$
   9. $v_r \leftarrow \sum_{y \in U_\nu} \left[ \max_{x \in U_\mu} f(x) R(x, y) \right] \nu(y)$
   10. if $v_l > v_r$ then
        $b \leftarrow$ false
        break
   11. end if
12. end for
13. return $b$

Algorithm 1 describes how Theorem 2 can be applied to numerically determine whether $\mu \sim_{st} \nu$. The interchange of the variables in the beginning corresponds to using (6) if the support of $\mu$ is smaller than $\nu$, and (7) otherwise. Inspection of Algorithm 1 shows that the computational complexity of determining whether $\mu \sim_{st} \nu$ is of the order
\[
O(\max(n'_1, n'_2) 2^\min(n'_1, n'_2)),
\]
where $n'_1$ and $n'_2$ denote the cardinalities of the supports of $\mu$ and $\nu$. The algorithm is very slow when both state spaces are large and $\mu$ and $\nu$ have positive mass in all states. However, in many applications related to structured Markov chains we may assume that the $\mu$ and $\nu$ have small supports (see Section 5).
Remark 1. The verification of $\mu \sim_{st} \nu$ can be carried out faster, if the underlying relation $R$ has some structure that can be employed. For example, for the natural order on $S = \{1, \ldots, n\}$, $\mu \leq_{st} \nu$ can be verified in $O(n^2)$ time by checking whether $\mu K \leq \nu K$ holds coordinatewise, where $K$ is the $n$-by-$n$ lower triangular matrix such that $K(i, j) = 1(i \geq j)$ [1].

3 Markov processes

3.1 Markovian couplings

All state spaces in the following shall be assumed finite or countably infinite. The keep the presentation short, all results shall be formulated for continuous-time Markov processes, which without further mention shall be assumed nonexplosive. For a Markov process $X$ with values in $S$ we denote by $X(x, t)$ the value of the process at time $t$ given that was started at state $x$. A Markov process $\hat{X} = (\hat{X}_1, \hat{X}_2)$ taking values in $S_1 \times S_2$ is called a Markovian coupling of $X_1$ and $X_2$ if $\hat{X}(x, t)$ couples $X_1(x_1, t)$ and $X_2(x_2, t)$ for all $t$ and all $x = (x_1, x_2)$. A common approach for showing that the time-dependent distributions of two Markov processes $X_1$ and $X_2$ are stochastically ordered, is to find a Markovian coupling $\hat{X} = (\hat{X}_1, \hat{X}_2)$ of $X_1$ and $X_2$ such that

$$x_1 \leq x_2 \implies \hat{X}_1(x_1, t) \leq \hat{X}_2(x_2, t)$$

almost surely for all $t$ [12]. Observe that if (8) holds, then for all $t$ and all increasing functions $f$,

$$E f(X_1(x_1, t)) = E f(\hat{X}_1(x_1, t))$$

$$\leq E f(\hat{X}_2(x_2, t)) = E f(X_2(x_2, t)),$$

whenever $x_1 \leq x_2$. Hence $X_1(x_1, t) \leq_{st} X_2(x_2, t)$. If both $X_1$ and $X_2$ have unique stationary distributions, it follows by taking limits that the stationary distributions are stochastically ordered.

Observe that (8) is not necessary for the stochastic ordering of the stationary distributions of $X_1$ and $X_2$. To formulate a less stringent sufficient condition, we shall use the following definitions. Let $R$ be a relation between $S_1$ and $S_2$. A pair of Markov processes $X_1$ in $S_1$ and $X_2$ in $S_2$ is said to stochastically preserve the relation $R$, if

$$x_1 \sim x_2 \implies X_1(x_1, t) \sim_{st} X_2(x_2, t) \text{ for all } t \geq 0.$$

Moreover, a set $B$ is called invariant for a Markov process $X$ if $x \in B$ implies $X(x, t) \in B$ for all $t$ almost surely. The following results was proved in [9], which we rephrase here for convenience.

Theorem 3. [9] The following are equivalent:

(i) $X_1$ and $X_2$ stochastically preserve the relation $R$. 

\( (ii) \) There exists a Markovian coupling of \( X_1 \) and \( X_2 \) for which \( R \) is invariant.

Assume now that \( X_1 \) and \( X_2 \) are Markov processes with values in an ordered space \( S \), and assume \( R \) is a subrelation of the order that is stochastically preserved by \( X_1 \) and \( X_2 \). Then \( X_1(x_1, t) \leq_{st} X_2(x_2, t) \) for all \( x_1 \sim x_2 \). Especially, if \( X_1 \) and \( X_2 \) have unique stationary distributions, then a sufficient condition for the stochastic ordering of the stationary distributions is that \( X_1 \) and \( X_2 \) stochastically preserve some nontrivial subrelation of the order relation.

### 3.2 Subrelation algorithm

Recall that a matrix \( Q \) with entries \( Q(x, y), x, y \in S \) is called a rate matrix, if \( Q(x, y) \geq 0 \) for all \( x \neq y \) and \( Q(x, x) = -\sum_{y \neq x} Q(x, y) \) for all \( x \). If \( X \) is a Markov process with rate matrix \( Q \), then \( Q(x, y) \) is the transition rate of \( X \) from state \( x \) into \( y \), and we denote by \( q(x) = -Q(x, x) \) the total transition rate of \( X \) out of state \( x \).

Given Markov processes \( X_1 \) and \( X_2 \) with rate matrices \( Q_1 \) and \( Q_2 \), define the relation-to-relation mapping \( M_{Q_1, Q_2} \) by

\[
M_{Q_1, Q_2}(R) = \{(x, y) \in R : (\mu_{x,y}, \nu_{x,y}) \in R_{st}\},
\]

where the probability measures \( \mu_{x,y} \) and \( \nu_{x,y} \) are defined by

\[
\mu_{x,y}(u) = q_{x,y}^{-1}Q_1(x, u) + \delta_x(u),
\]

\[
\nu_{x,y}(v) = q_{x,y}^{-1}Q_2(y, v) + \delta_y(v),
\]

and where \( q_{x,y} = 1 + q_1(x) + q_2(y) \). When there is no risk of confusion, we denote \( M_{Q_1, Q_2} = M \). Moreover, define recursively the sequence \( M^k(R) \) by setting \( M^0(R) = R \), \( M^k(R) = M(M^{k-1}(R)) \) for \( k \geq 1 \), and denote the limit of the sequence by

\[
M^*(R) = \cap_{k=0}^\infty M^k(R).
\]

**Theorem 4.** [9] The relation \( M^*(R) \) is the maximal subrelation of \( R \) that is stochastically preserved by \( X_1 \) and \( X_2 \). Especially:

\( (i) \) \( X_1 \) and \( X_2 \) stochastically preserve \( R \) if and only if \( M(R) = R \).

\( (ii) \) \( X_1 \) and \( X_2 \) stochastically preserve a nontrivial subrelation of \( R \) if and only if \( M^*(R) \neq \emptyset \).

When the state spaces \( S_1 \) and \( S_2 \) are finite, Algorithm 2 describes how to numerically compute \( M(R) \), and Algorithm 3 describes the computation of \( M^*(R) \). Observe that for finite state spaces, Algorithm 3 computes the apparently infinite intersection \( \cap_{k=0}^\infty M^k(R) \) in finite time, because as long as \( M^k(R) \) and \( M^{k-1}(R) \) are not equal, they differ by at least one element, and the sequence \( M^k(R) \) is decreasing.
Algorithm 2 Computation of $R' = M(R)$.  

$$R' \leftarrow n_1 \times n_2 \text{ zero matrix}$$

for $(x, y) \in R$ do

$q \leftarrow 1 + q^{(1)}(x) + q^{(2)}(y)$

$\mu \leftarrow q^{-1}Q^{(1)}(x, \cdot) + \delta_x(\cdot)$

$\nu \leftarrow q^{-1}Q^{(2)}(y, \cdot) + \delta_y(\cdot)$

Check whether $\mu \sim_{st} \nu$ (use Algorithm 1)

if $\mu \sim_{st} \nu$ then

$R'(x, y) \leftarrow 1$

end if

end for  

Algorithm 3 Computation of $R^* = \cap_{n=0}^{\infty} M^k(R)$.  

$$R' \leftarrow M(R) \text{ (use Algorithm 2)}$$

while $R' \neq R$ do

$R \leftarrow R'$

$R' \leftarrow M(R) \text{ (use Algorithm 2)}$

end while

$R^* \leftarrow R'$  

4 Truncation approach  

4.1 Truncation of Markov processes  

If $Q$ is a rate matrix of a Markov process on a countably infinite space $S$, and $S_n$ is a finite subset of $S$, we define the truncation of $Q$ into $S_n$ by

$$Q_n(x, y) = \begin{cases} 
Q(x, y), & x \neq y, \ x, y \in S_n, \\
- \sum_{y \in S_n, y \neq x} Q(x, y), & x = y, \ x \in S_n.
\end{cases}$$

(12)

We shall later approximate $Q$ by $Q_n$ and use the finite subrelation algorithm applied to $Q_n$. To understand the approximation error, we need to study how the untruncated process may escape the set $S_n$. Given a rate matrix $Q$ on a countable space $S$, we say that an increasing sequence of finite sets $S_n \subset S$ is a truncation sequence for $Q$, if $\cup_{n=0}^{\infty} S_n = S$, and

$$\{y : Q(x, y) > 0\} \subset S_{n+1}$$

(13)

for all $x \in S_n$.

Example 2. Let $Q$ be the rate matrix of a Markov process on $\mathbb{Z}_+$ that is skip-free to the right, so that $Q(i, j) = 0$ for all $j > i + 1$. Then $S_n = \mathbb{Z}_+ \cap [0, n]$ is truncation sequence for $Q$.

The next result shows that truncation sequences can be constructed for most Markov processes encountered in applications. We say that a Markov process $X$ with rate matrix $Q$ has locally bounded jumps, if the set $\{y : Q(x, y) > 0\}$ is finite for all $x$.  

9
Lemma 1. Any rate matrix $Q$ of a Markov process with locally bounded jumps possesses a truncating sequence.

Proof. Because $S$ is countable, we may choose an increasing sequence of finite sets $K_n$ such that $\bigcup_{n=0}^{\infty} K_n = S$. Using this sequence we may recursively define the sets $S_n$ by setting $S_0 = K_0$, and

$$S_{n+1} = S_n \cup K_n \cup J(S_n), \quad n \geq 0,$$

denotes the set of states that are reachable from $S_n$ by one jump. Then $\bigcap_{n=0}^{\infty} S_n = S$, because $K_n \subset S_{n+1}$ for all $n \geq 0$. Moreover, $J(S_n) \subset S_{n+1}$ implies that (13) holds for all $n$, and induction shows that the sets $S_n$ are finite, because $Q$ has locally bounded jumps. \hfill $\square$

4.2 Truncation of stochastic relations

Let $R$ be a relation between countably infinite state spaces $S_1$ and $S_2$. If $S'_i$ is a finite subset of $S_i$, $i = 1, 2$, we define the truncation of $R$ by

$$R' = R \cap (S'_1 \times S'_2) \quad (14)$$

The corresponding stochastic relation $R'_{st}$, a relation between probability measures on the finite spaces $S'_1$ and $S'_2$, is called the truncation of $R_{st}$ into $S'_1 \times S'_2$.

If $\mu_i$ is probability measure on $S_i$ having all its mass on $S'_i$, we may regard $\mu_i$ as a probability measure $\mu'_i$ on $S'_i$ by identifying subsets of $S'_i$ as subsets of $S_i$.

Lemma 2. Let $\mu_i$ be a probability measure on $S_i$ such that $\mu_i(S'_i) = 1$, $i = 1, 2$. Then $(\mu_1, \mu_2) \in R_{st}$ if and only if $(\mu'_1, \mu'_2) \in R'_{st}$.

Proof. The claim follows using [9, Lemma 5.2], after observing that $R'$ is the relation induced from $R$ by the pair $(\phi_1, \phi_2)$, where $\phi_i$ is the natural embedding of $S'_i$ into $S_i$, and $\mu'_i = \mu_i \circ \phi_i$. \hfill $\square$

4.3 Truncated subrelation algorithm

Given a pair of Markov processes $X_1$ and $X_2$ with rate matrices $Q_1$ and $Q_2$, and a relation $R$ between $S_1$ and $S_2$, Algorithm 3 describes how to recursively calculate $R^* = M^{*,Q_2,Q_1}(R)$ as the limit of the sequence $R^k = M^{k,Q_1,Q_2}(R)$. If the state spaces are infinite, $R^k$ cannot be computed using finite time and memory. Nevertheless, when the processes have locally bounded jumps, the truncations $T_N(R^k)$ of $R^k$ into suitable truncation sets $S_{1,N} \times S_{2,N}$ can be computed precisely, as shall be shown next.

For any relation $R$ between $S_{1,n}$ and $S_{2,n}$, let $M_n(R) = M_{Q_{1,n},Q_{2,n}}(R)$ be the relation given by Algorithm 2 applied to $R$ using the truncations $Q_{1,n}$ and $Q_{2,n}$ of $Q_1$ and $Q_2$ as defined in (13). Moreover, denote by $M_\infty = M_{Q_1,Q_2}$ the corresponding untruncated mapping.
Lemma 3. For any pair of Markov processes with locally bounded jumps, the truncation of $M_\infty(R)$ to $S_{1,n} \times S_{2,n}$ satisfies

$$T_n(M_\infty(R)) = T_n(M_{n+1}(T_{n+1}(R))) \quad \text{for all } n.$$ 

Proof. Observe that $T_n(M_\infty(R))$ equals the set of points $(x, y) \in T_n(R)$ such that the measures $\mu_{x,y}$ and $\nu_{x,y}$ defined in (10) and (11) are stochastically related with respect to $R$. Because $S_{1,n}$ and $S_{2,n}$ are truncating sequences for $Q_1$ and $Q_2$, we know that $\mu_{x,y}$ and $\nu_{x,y}$ have supports in $S_{1,n+1}$ and $S_{2,n+1}$, respectively. Hence by Lemma 2, $T_n(M_\infty(R))$ equals the set of points $(x, y) \in T_n(R)$ such that $\mu_{x,y}$ and $\nu_{x,y}$ are stochastically related with respect to $T_{n+1}(R)$. Because for $(x, y) \in T_n(R)$, the measures $\mu_{x,y}$ and $\nu_{x,y}$ remain the same, if we replace $Q_1$ and $Q_2$ by $Q_{1,n+1}$ and $Q_{2,n+1}$ in (10) and (11), the claim follows. 

Theorem 5. For any pair of Markov processes with locally bounded jumps, the truncation of $R^k = M^k_\infty(R)$ to $S_{1,n} \times S_{2,n}$ satisfies

$$T_n(R^k) = T_n(M_{n+1}T_{n+1}) \cdots (M_{n+k}T_{n+k})(R).$$

Proof. Apply Lemma 3 and induction. 

Algorithm 4 describes how Theorem 5 can be used to compute $T_n(R^k)$ in finite time and memory.

\begin{algorithm}
\caption{Computation of $R' = T_N(M^K(R))$.}
$R' \leftarrow T_{N+K}(R)$
\FOR{$k = 1, \ldots, K$} 
\STATE $n \leftarrow N + K + 1 - k$
\STATE $Q_{1,n} \leftarrow$ truncation of $Q_1$ into $S_{1,n}$
\STATE $Q_{2,n} \leftarrow$ truncation of $Q_2$ into $S_{2,n}$
\STATE $R' \leftarrow T_n(R')$
\STATE $R' \leftarrow$ Algorithm 2 applied to $(Q_{1,n}, Q_{2,n}, R')$
\ENDFOR
\STATE $R' \leftarrow T_N(R')$
\end{algorithm}

The following result is a necessary condition for finding a subrelation of $R$ that is stochastically preserved by a pair of Markov processes.

Theorem 6. Let $X_1$ and $X_2$ be Markov processes with locally bounded jumps. If $T_n(M^k(R)) = \emptyset$ for some $k$, then $T_n(M^*(R)) = \emptyset$. Especially, if for all $n$, $T_n(M^k(R)) = \emptyset$ for some $k$, then $X_1$ and $X_2$ do not stochastically preserve any nontrivial subrelation of $R$.

Proof. Because the sequence $M^k(R)$ is decreasing, and because the truncation map is monotone with respect to set inclusion, the first claim follows. For the second claim, observe that if $T_n(R^*) = \emptyset$ for all $n$, then because $\cup_n (S_{1,n} \times S_{2,n}) = S$, $R^* = \emptyset$.

5.1 Multilayer loss networks

5.1.1 Overflow routing

Consider a loss system with $K$ customer classes and two layers of servers, where layer 1 contains $m_k$ servers dedicated to class $k$, and layer 2 consists of $n$ servers capable of serving all customer classes. Arriving class-$k$ customers are routed to vacant servers in one of the layers, with preference given to layer 1; or rejected otherwise. For analytical tractability, we assume that the interarrival times and the service requirements of class-$k$ customers are exponentially distributed with parameters $\lambda_k$ and $\mu_k$, respectively, and that all these random variables across all customer classes are independent. For brevity, we denote $m = (m_1, \ldots, m_K)$, $\lambda = (\lambda_1, \ldots, \lambda_K)$, and $\mu = (\mu_1, \ldots, \mu_K)$.

![Diagram of a two-layer loss network with three customer classes ($K = 3$).](image)

Denote by $X_{i,k}(t)$ the number of class-$k$ customers being served at layer $i$ at time $t$. The system is described by the Markov process $X = (X_{i,k})$ taking values in

$$S_1 = \left\{ x \in \mathbb{Z}_+^K \times \mathbb{Z}_+^K : x_{1,k} \leq m_k \text{ } \forall k, \sum_{k=1}^{K} x_{2,k} \leq n \right\}, \quad (15)$$

and having the transitions

$$x \mapsto \begin{cases} 
 x + e_{1,k}, & \text{at rate } \lambda_k1(x_{1,k} < m_k), \\
 x + e_{2,k}, & \text{at rate } \lambda_k1(x_{1,k} = m_k, \sum_{k=1}^{K} x_{2,k} < n), \\
 x - e_{1,k}, & \text{at rate } \mu_k x_{1,k}, \\
 x - e_{2,k}, & \text{at rate } \mu_k x_{2,k},
\end{cases}$$

where $e_{i,k}$ denotes the unit vector in $\mathbb{Z}_+^K \times \mathbb{Z}_+^K$ corresponding to the coordinate direction $(i, k)$.

5.1.2 Maximum packing

To approximate the original two-layer loss system, we consider a modification of the system, where customers are redirected from layer 2 to layer 1 as
soon as servers become vacant. This corresponds to the so-called maximum packing policy introduced by Everitt and Macfadyen [4]. Denote by \( Y(t) \) the total number of customers in the system with maximum packing. Then \( t \mapsto Y(t) = (Y_1(t), \ldots, Y_K(t)) \) is a Markov process (see [5]) with values in

\[
S_2 = \left\{ y \in \mathbb{Z}_+^K : \sum_{k=1}^K (y_k - m_k)_+ \leq n \right\},
\]

and having the transitions

\[
y \mapsto \begin{cases} 
y + e_k, & \text{at rate } \lambda_k(y + e_k \in S_2), \\
y - e_k, & \text{at rate } \mu_k y_k. 
\end{cases}
\]

The structure of the above transition rates implies that the stationary distribution \( \pi_Y \) of \( Y \) is a product of Poisson distributions truncated to \( S_2 \) [7], so that

\[
\pi_Y(y) = c \prod_{k=1}^K \left( \frac{\lambda_k}{\mu_k} \right)^{y_k} \frac{y_k!}{y_k}, \quad y \in S_2,
\]

where the constant \( c \) can be solved from \( \sum_{y \in S_2} \pi_Y(y) = 1 \). This product form structure allows for fast computation of stationary performance characteristics of the maximum packing system.

5.1.3 Stochastic comparison

Table 1 illustrates the outcomes of the subrelation algorithm (computed using [8]) applied to various initial relations, where

\[
R^\text{sum} = \left\{ (x, y) \in S_1 \times S_2 : \sum_k (x_{1,k} + x_{2,k}) \leq \sum_k y_k \right\},
\]

\[
R^\text{sum}_1 = \left\{ (x, y) \in S_1 \times S_2 : \sum_k x_{1,k} \leq \sum_k (y_k \land m_k) \right\},
\]

\[
R^\text{coord}_1 = \left\{ (x, y) \in S_1 \times S_2 : x_{1,k} \leq y_k \land m_k \text{ for all } k \right\}.
\]

Note that \( R^\text{sum}_1 \) relates the state pairs \((x, y)\) where the total number of layer-1 customers corresponding to \( x \) is less than that corresponding to \( y \). Moreover, \( R^\text{coord}_1 \) relates the state pairs where the populations in layer 1 are coordinate-wise ordered. The entry ’several’ in Table 1 refers to running Algorithm 2 separately for several pseudorandom parameter combinations, and taking the intersection of the produced relations as a final result.

From Table 1, we can make several conclusions on the behavior of the subrelation algorithm:

• The pair \((X_1, X_2)\) appears to stochastically preserve \( R^\text{sum}_1 \) for all parameter combinations (same parameters in both systems). This fact is in fact not hard to verify analytically.

• When \( \mu_1 = \mu_2 \), the pair \((X_1, X_2)\) stochastically preserves a nontrivial subrelation of \( R^\text{sum} \). The maximal subrelation of \( R^\text{sum} \) preserved may depend on the model parameters.
Table 1: Outcomes of the subrelation algorithm for a network with \( m_1 = 1, m_2 = 1, n = 2 \).

<table>
<thead>
<tr>
<th>( R )</th>
<th>(( \lambda_1, \lambda_2 ))</th>
<th>(( \mu_1, \mu_2 ))</th>
<th>( M^*(R) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( R_{\text{sum}} )</td>
<td>(1, 1)</td>
<td>(1, 1)</td>
<td>( R_{\text{sum}} \cap R_{1_{\text{sum}}} \cap R_{1_{\text{min}}} )</td>
</tr>
<tr>
<td>( R_{\text{sum}} )</td>
<td>several</td>

<td>several</td>
<td>several</td>
<td>( \emptyset )</td>
</tr>
</tbody>
</table>

- \( R_{\text{sum}} \cap R_{1_{\text{coord}}} \) appears to be a subrelation of \( R_{\text{sum}} \) that is stochastically preserved for all parameter choices, as long as \( \mu_1 = \mu_2 \) (Figure 3). This fact is proved in [5].

- When the system is symmetric (\( \lambda_1 = \lambda_2, \mu_1 = \mu_2 \) and \( m_1 = m_2 \)), a larger relation \( R_{\text{sum}} \cap R_{1_{\text{sum}}} \cap R_{1_{\text{min}}} \supset R_{\text{sum}} \cap R_{1_{\text{coord}}} \) is stochastically preserved (Figure 2).

- When \( \mu_1 \neq \mu_2 \), \( R_{\text{sum}} \) in general does not have a nontrivial subrelation preserved by the pair. This fact is also reflected in [5, Example 5.2.1], where it was found that the stationary distributions are not in general stochastically ordered with respect to \( R_{\text{sum}} \).

As an illustration, the limiting relations \( R_{\text{sum}} \cap R_{1_{\text{sum}}} \cap R_{1_{\text{min}}} \) and \( R_{\text{sum}} \cap R_{1_{\text{coord}}} \) (filled circles), together with the initial relation \( R_{\text{sum}} \) (filled + unfilled circles) are plotted in Figures 2 and 3, respectively.

Figure 2: Relations \( R_{\text{sum}} \) and \( M^*(R_{\text{sum}}) \) for a system with \( m_1 = 1, m_2 = 1, n = 2 \), for \( \lambda = (1, 1) \) and \( \mu = (1, 1) \).
5.2 Parallel queues

Consider a system of two queues in parallel, where customers of queue $k$ have arrival rate $\lambda_k$ and service rate $\mu_k$. Assuming that all interarrival and service times are independent and exponential, the queue length process $X = (X_1, X_2)$ is a Markov process in $\mathbb{Z}_+^2$ with transitions

$$
X \mapsto \begin{cases}
  x + e_k, & \text{at rate } \lambda_k, \\
  x - e_k, & \text{at rate } \mu_k1(x_k > 0).
\end{cases}
$$

We shall also consider a modification of the system, where load is balanced by routing incoming traffic to the shortest queue, modeled as a Markov process $X^{LB} = (X_1^{LB}, X_2^{LB})$ in $\mathbb{Z}_+^2$ with transitions

$$
X \mapsto \begin{cases}
  x + e_1, & \text{at rate } (\lambda_1 + \lambda_2)1(x_1 < x_2) + \lambda_11(x_1 = x_2), \\
  x + e_2, & \text{at rate } (\lambda_1 + \lambda_2)1(x_1 > x_2) + \lambda_21(x_1 = x_2), \\
  x - e_1, & \text{at rate } \mu_11(x_1 > 0), \\
  x - e_2, & \text{at rate } \mu_21(x_2 > 0).
\end{cases}
$$

Common sense suggests that load balancing decreases the number of customers in the system in some sense. The validity of this comparison property can be numerically studied using Algorithm 4. Denote the rate matrix of $X^{LB}$ by $Q_1$ and the rate matrix of $X$ by $Q_2$, and let $S_n = \mathbb{Z}_+^2 \cap [0, n-1]^2$, $n \geq 1$. Then $S_n$ is a truncation sequence for both $Q_1$ and $Q_2$.

Figure 4 illustrates five iterations of the subrelation algorithm (computed using [8]) truncated to $S_3$ applied to the coordinatewise order

$$
R^{\text{coord}} = \{(x, y) \in \mathbb{Z}_+^2 \times \mathbb{Z}_+^2 : x_1 \leq y_1, \ x_2 \leq y_2\},
$$

with the parameters $\lambda_1, \lambda_2, \mu_1, \mu_2$ all equal to one. Because $T_3(R^1) = T_3(R^5) = \emptyset$, we conjecture that there exists no nontrivial subrelation of $R^{\text{coord}}$ stochastically preserved by $(X^{LB}, X)$ (see Theorem 6).
Figure 4: Truncated subrelation algorithm applied to $R^\text{coord}$.

Let us next study another order on $\mathbb{Z}_2^+$, defined by

$$R^\text{sum} = \{ (x, y) \in \mathbb{Z}_2^+ \times \mathbb{Z}_2^+ : x_1 + y_1, x_2 + y_2 \}.$$

Figure 5 illustrates five iterations of the subrelation algorithm (computed using [8]) truncated to $S_3$ applied to $R^0 = R^\text{sum}$ with the parameters $\lambda_1, \lambda_2, \mu_1, \mu_2$ all equal to one. The observation that $T_3(R^k)$ remains unchanged from $k = 1$ onwards suggests that some nontrivial subrelation of $R^\text{sum}$ might be stochastically preserved by $(X^\text{LB}, X)$. Indeed, it has been analytically shown [9] that whenever $\mu_1 = \mu_2$, the untruncated subrelation algorithm converges to the relation

$$R^* = \{ (x, y) : x_1 + x_2 \leq y_1 + y_2 \text{ and } x_1 \lor x_2 \leq y_1 \lor y_2 \}.$$

As a consequence of Theorem 4, the pair $(X^\text{LB}, X)$ stochastically preserves the relation $R^*$, which may be identified as the weak majorization order on $\mathbb{Z}_2^+$ [10]. Especially,

$$X_1^\text{LB}(t) + X_2^\text{LB}(t) \leq_{\text{st}} X_1(t) + X_2(t),$$
$$X_1^\text{LB}(t) \lor X_2^\text{LB}(t) \leq_{\text{st}} X_1(t) \lor X_2(t),$$

for all $t$, whenever the initial states $X^\text{LB}(0)$ and $X(0)$ satisfy the same inequalities.
6 Conclusions

This paper presented computational methods for verifying stochastic relations and finding relation-invariant couplings of continuous-time Markov processes on finite and countably infinite state spaces. A key point of the paper is that the stochastic relationship between two probability measures can be quickly numerically checked, if one of the measures has small support (Theorem 2). This result allows the development of a truncation approach for finding relations stochastically preserved by pairs of Markov processes with locally bounded jumps. The truncated subrelation algorithm (Algorithm 4) allows to numerically find candidates for a subrelation of a given relation that is stochastically preserved by a pair of Markov processes. It remains an interesting open problem for future research to study how the truncated subrelation algorithm behaves for structured Markov processes with for example shift-invariant transition rate matrices.
