A POSTERIORI ANALYSIS FOR PDE’s.

S. Repin,

V.A. Steklov Institute of Mathematics in St.-Petersburg
Lecture 1. FIRST APPROACHES TO A POSTERIORI ERROR CONTROL

- Error estimation problem in computer simulation
- Mathematical background
- A priori error estimation methods
- Runge’s rule
- The estimate of Prager and Synge
- The estimate of Mikhlin
- A posteriori estimates of Ostrowski for contractive mappings
- A posteriori methods based on monotonicity

Lecture 2. A POSTERIORI ERROR ESTIMATION METHODS FOR FEM

- Sobolev spaces with negative indices
- Errors and Residuals. First glance
- Residual type estimates for elliptic equations
- Explicit residual method in 1D case
- Explicit residual method in 2D case
- A posteriori error indicators based on post-processing of computed solutions
- General idea
- Post-processing by averaging
Superconvergence
Post-processing by equilibration
A posteriori error estimates constructed with help of adjoint problems

3 FUNCTIONAL A POSTERIORI ESTIMATES FOR A MODEL ELLIPTIC PROBLEM

- Deriving functional a posteriori estimates by the variational method
- Deriving functional a posteriori estimates by the non-variational method
- Properties of functional a posteriori estimates
- How to use the estimates in practice?

4 Two-sided a posteriori estimates for linear elliptic problems

- Problem in the abstract form
- Upper bounds of the error
- Lower bounds of the error
- Computability of two-sided estimates
- Relationships with other methods
- Diffusion problem
- Linear elasticity problem
- Elliptic equations of the 4th order

5 A POSTERIORI ESTIMATES IN NON-ENERGY QUANTITIES

- General principle
A posteriori estimates for mixed methods

Mixed formulations of elliptic problems
- Primal Mixed Finite Element Method
- Dual Mixed Finite Element Method
- A priori error estimates for Dual Mixed Finite Element Method
- Functional a posteriori estimates for mixed approximations

Mixed FEM on distorted meshes
- Distorted meshes
- Extension of fluxes inside a cell
- Well-posedness of discrete problems
- Examples of extension operators
- A priori rate convergence estimates
- Inf-sup condition
- A posteriori estimates

A posteriori estimates for problems in the theory of viscous fluids
Mathematical models of viscous fluids

Stokes problem

Inf–Sup condition

Existence of a saddle–point

Estimates of the distance to the set of solenoidal fields

A posteriori estimates for the Stokes problem

Estimates for almost incompressible fluids

Generalizations

Nonlinear models of viscous fluids

Antiplane flow of Bingham fluid

Functional a posteriori estimates for generalized Newtonian fluids

A POSTERIORI ESTIMATES FOR NONLINEAR VARIATIONAL PROBLEMS

Abstract variational problem

Dual and bidual functionals

Compound functionals

Uniformly convex functionals

General form of the functional a posteriori estimate

Example. Diffusion problem with Robin boundary conditions
This is the electronic version of the lecture course

Mat-5.210 Special Course in Computational Mechanics Autumn 2006:  
"A POSTERIORI ANALYSIS FOR PDE’s"  
http://math.tkk.fi/teaching/lme/

that was prepared for students and PhD students of the Department of Mathematics of Helsinki University of Technology and read in 2006. In general, it is aimed to give an answer to the question ”How to verify the accuracy of approximate solutions of partial differential equations computed by various numerical methods ?” A posteriori error estimates present a tool able to give an answer to the above question. Nowadays a posteriori estimates form a basis of many powerful numerical techniques and are widely used in computational technologies. Therefore, the purpose of the course is to discuss the main lines in a posteriori analysis and explain their mathematical foundations.
First, the ”classical” a posteriori error estimation methods developed for finite element approximations are considered. However, the major part of the course is devoted to a new functional approach to a posteriori error estimation developed in the last decade. Basic ideas of this approach are first explained on the paradigm of a simple elliptic problem. Further exposition contains applications to particular classes of problems: diffusion, linear elasticity, Stokes, biharmonic, variational inequalities, etc.

The material is based on earlier lectures on a posteriori estimates and adaptive methods that has been read by the author at the University of Houston, USA (2002); University of Jyväskylä, Finland (2003), Radon Institute of Computational and Applied Mathematics (RICAM) in Linz (2005), and at St.-Petersburg Polytechnical University (2000-2003). However, in general, the course is new. A special attention is paid on a posteriori error estimation methods for two important classes of problems that are now in the focus of numerous researches in numerical analysis, namely to mixed FE approximations and approximations in the theory of viscous fluids.
Full list of references is given at the end of the text, but certain key publications are also cited in the respective places related to the topic discussed.

I wish to express my gratitude to Helsinki University of Technology for the invitation and hospitality. I am grateful to Prof. R. Stenberg for his kind support and interesting discussions that helped to create the course in the present form and also to Mr. A. Niemi and Mrs. Tuula–Donskoi for their help during my visit.

Sergey Repin

Espoo, November 2006
Lecture 1

The goal of the lecture is to provide a background information, shortly discuss the a priori error estimation methods and to give a concise overview of first a posteriori error estimation methods.
Lecture plan

- Error estimation problem in computer simulation;
- A priori approach to the error analysis for PDE’s;
- A posteriori methods developed in 1900–1975:
  - Heuristic Runge’s rule;
  - Prager and Synge estimate;
  - Estimate of Mikhlin;
  - Estimates of Ostrowski for contractive mappings;
  - Estimates based on monotonicity (Collatz);
Let us begin with a ”philosophic” question:

WHAT THE NUMBERS COMPUTED INDEED MEAN?
To convince yourself that the question stated is worth thinking out, please make

**Task 1. ”Baby” coupled problem.**

\[ z'' - 9z' - 10z = 0, \quad z = z(x), \quad x \in [0, 8], \]

\[ z(0) = 1, \quad z'(0) = a_{N-1} - a_N, \]

where \( a \) is a solution of the system of the dimensionality \( N \)

\[ Ba = f, \quad b_{ij} = \frac{2S^2_i S^2_j}{\pi} \int_{0}^{\pi} \left( \sin(i\xi) \sin(j\xi) + \sin(i + j^2)\xi \right) \, d\xi, \]

\[ i, j = 1, 2, \ldots N, \quad f_i = (i + 1)^4 i, \quad S_i = \sum_{k=0}^{+\infty} \left( \frac{i}{i + 1} \right)^k. \]
The task

For \( N = 10, 50, 100, 200 \) find \( z(8) \) analytically and compare with numerical results obtained by computing the sums numerically, finding definite integrals with help of quadratures formulas, solving the system of linear simultaneous equations by a numerical method, and integrating the differential equation by a certain (e.g., Euler) method.
I. In the vast majority of cases, exact solutions of differential equations are unknown. We have no other way to use differential equations in the mathematical modeling other than compute approximate solutions and analyze computer simulation results.

II. Approximate solutions contain errors of various nature.

From I and II, it follows that

III. Verification of the accuracy of approximate solutions a KEY QUESTION.
Errors in mathematical modeling

\( \varepsilon_1 \) – error of a mathematical model used

\( \varepsilon_2 \) – approximation error arising when a differential model is replaced by a discrete one;

\( \varepsilon_3 \) – numerical errors arising when solving a discrete problem.
Let $U$ be a physical value that characterizes some process and $u$ be a respective value obtained from the mathematical model. Then the quantity

$$\varepsilon_1 = |U - u|$$

is an error of the mathematical model.

Mathematical model always presents an "abridged" version of a physical object.

Therefore, $\varepsilon_1 > 0$. 
TYPICAL SOURCES OF MODELING ERRORS

(a) "Second order" phenomena are neglected in a mathematical model.

(b) Problem data are defined with an uncertainty.

(c) Dimension reduction is used to simplify a model.
Let $u_h$ be a solution on a mesh of the size $h$. Then, $u_h$ encompasses the approximation error

$$\varepsilon_2 = |u - u_h|.$$ 

Classical error control theory is mainly focused on approximation errors.
NUMERICAL ERRORS

Finite–dimensional problems are also solved approximately, so that instead of \( u_h \) we obtain \( u_h^\varepsilon \). The quantity

\[
\varepsilon_3 = |u_h - u_h^\varepsilon|
\]

shows an error of the numerical algorithm performed with a concrete computer. This error includes

- roundoff errors,
- errors arising in iteration processes and in numerical integration,
- errors caused by possible defects in computer codes.
Roundoff errors

Numbers in a computer are presented in a floating point format:

\[ x = \pm \left( \frac{i_1}{q} + \frac{i_2}{q^2} + \ldots + \frac{i_k}{q^k} \right) q^\ell, \quad i_s < q. \]

These numbers form the set \( R_{q^\ell k} \subset \mathbb{R}. \)

\( q \) is the base of the representation,

\( \ell \in [\ell_1, \ell_2] \) is the power.

\( R_{q^\ell k} \) is not closed with respect to the operations \( +, -, \cdot \).
The set $R_{q\ell_k} \times R_{q\ell_k}$
Example

\[ k = 3, \quad a = \left( \frac{1}{2} + 0 + 0 \right) \times 2^5, \quad b = \left( \frac{1}{2} + 0 + 0 \right) \times 2^1 \]

\[ b \Rightarrow \left( 0 + \frac{1}{2} + 0 \right) \times 2^2 \Rightarrow \left( 0 + 0 + \frac{1}{2} \right) \times 2^3 \Rightarrow (0 + 0 + 0) \times 2^4 \]

\[ a + b = a!!! \]

**Definition.** The smallest floating point number which being added to 1 gives a quantity other than 1 is called **the machine accuracy**.
Numerical integration

\[
\int_{a}^{b} f(x) \, dx \approx \sum_{i=1}^{n} c_i f(x_i) h = \sum_{i=1}^{n/2} c_i f(x_i) h + c_{n/2+1} f(x_{n/2+1}) h + \ldots
\]
Errors in computer simulation

\[ U \quad \text{Physical object/process} \]
\[ \Downarrow \]
\[ \varepsilon_1 \quad \rightarrow \quad \text{Error of a model} \]
\[ \Downarrow \]
\[ u \quad \text{Differential model} \quad Au = f \]
\[ \Downarrow \]
\[ \varepsilon_2 \quad \rightarrow \quad \text{Approximation error} \]
\[ \Downarrow \]
\[ u_h \quad \text{Discrete model} \quad A^h u_h = f_h \]
\[ \Downarrow \]
\[ \varepsilon_3 \quad \rightarrow \quad \text{Computational error} \]
\[ \Downarrow \]
\[ u_h^\varepsilon \quad \text{Numerical solution} \quad A^h u_h^\varepsilon = f_h + \varepsilon. \]
Two principal relations

I. Computations on the basis of a reliable (certified) model. Here $\varepsilon_1$ is assumed to be small and $u_h^\varepsilon$ gives a desired information on $U$.

$$\| U - u_h^\varepsilon \| \leq \varepsilon_1 + \varepsilon_2 + \varepsilon_3.$$  \hfill (1)

II. Verification of a mathematical model. Here physical data $U$ and numerical data $u_h^\varepsilon$ are compared to judge on the quality of a mathematical model

$$\| \varepsilon_1 \| \leq \| U - u_h^\varepsilon \| + \varepsilon_2 + \varepsilon_3.$$  \hfill (2)
Thus, two major problems of mathematical modeling, namely,

- reliable computer simulation,
- verification of mathematical models by comparing physical and mathematical experiments,

require efficient methods able to provide computes and realistic estimates of $\varepsilon_2 + \varepsilon_3$. 
What is $u$ and what is $\| \cdot \|$?

If we start a more precise investigation, then it is necessary to answer the question

What is a solution to a boundary–value problem?

Example.

$$\frac{\partial^2 u}{\partial x_1^2} + \frac{\partial^2 u}{\partial x_2^2} + f = 0, \quad u = u_0 \text{ on } \partial \Omega \quad \exists u?.$$  

It is not a trivial question, so that about one hundred years passed before mathematicians have found an appropriate concept for PDE’s.
Without proper understanding of a mathematical model no real modeling can be performed. Indeed,

If we are not sure that a solution $u$ exists then what we try to approximate numerically?

If we do not know to which class of functions $u$ belongs to, then we cannot properly define the measure for the accuracy of computed approximations.

Thus, we need to recall a

**CONCISE MATHEMATICAL BACKGROUND**
Vectors and tensors

\( \mathbb{R}^n \) contains real \( n \)-vectors. \( \mathbb{M}^{n\times m} \) contains \( n \times m \) matrices and \( \mathbb{M}_s^{n\times n} \) contains \( n \times n \) symmetric matrices (tensors) with real entries.

\[
\mathbf{a} \cdot \mathbf{b} = \sum_{i=1}^{n} a_i b_i \in \mathbb{R}, \quad \mathbf{a}, \mathbf{b} \in \mathbb{R}^n \quad \text{(scalar product of vectors)},
\]

\[
\mathbf{a} \otimes \mathbf{b} = \{a_i b_j\} \in \mathbb{M}^{n\times n} \quad \text{(tensor product of vectors)},
\]

\[
\mathbf{\sigma} : \mathbf{\varepsilon} = \sum_{i,j=1}^{n} \sigma_{ij} \varepsilon_{ij} \in \mathbb{R}, \quad \mathbf{\sigma}, \mathbf{\varepsilon} \in \mathbb{M}^{n\times n} \quad \text{(scalar product of tensors)}.
\]

\[
|\mathbf{a}| := \sqrt{\mathbf{a} \cdot \mathbf{a}}, \quad |\mathbf{\sigma}| := \sqrt{\mathbf{\sigma} : \mathbf{\sigma}},
\]

Unit matrix is denoted by \( \mathbb{I} \). If \( \mathbf{\tau} \in \mathbb{M}^{n\times n} \), then \( \mathbf{\tau}^D = \mathbf{\tau} - \frac{1}{n} \mathbb{I} \) is the deviator of \( \mathbf{\tau} \).
Spaces of functions

Let $\Omega$ be an open bounded domain in $\mathbb{R}^n$ with Lipschitz continuous boundary.

$C^k(\Omega)$ – $k$ times continuously differentiable functions.

$C_0^k(\Omega)$ – $k$ times continuously differentiable functions vanishing at the boundary $\partial \Omega$.

$C_0^\infty(\Omega)$ – $k$ smooth functions with compact supports in $\Omega$.

$L^p(\Omega)$ – summable functions with finite norm

$$\|g\|_{p,\Omega} = \|g\|_p = \left(\int_{\Omega} |g|^p\right)^{1/p}.$$ 

For $L^2(\Omega)$ the norm is denoted by $\|\cdot\|$. 
If \( g \) is a vector (tensor)–valued function, then the respective spaces are denoted by

\[
\mathcal{C}^k(\Omega, \mathbb{R}^n) \ (\mathcal{C}^k(\Omega, \mathbb{M}^{n \times n})) ,
\]
\[
L^p(\Omega, \mathbb{R}^n) \ (L^p(\Omega, \mathbb{M}^{n \times n}))
\]

with similar norms.

We say that \( g \) is **locally integrable** in \( \Omega \) and write \( f \in L^{1,\text{loc}}(\Omega) \), if \( g \in L^1(\omega) \) for any \( \omega \subset \subset \Omega \). Similarly, one can define the space \( L^{p,\text{loc}}(\Omega) \) that consists of functions locally integrable with degree \( p \geq 1 \).
Generalized derivatives

Let \( f, g \in L^{1, \text{loc}}(\Omega) \) and

\[
\int_{\Omega} g \varphi \, dx = - \int_{\Omega} f \frac{\partial \varphi}{\partial x_i} \, dx, \quad \forall \varphi \in C^1(\Omega).
\]

Then \( g \) is called a \textbf{generalized derivative} (in the sense of Sobolev) of \( f \) with respect to \( x_i \) and we write

\[
g = \frac{\partial f}{\partial x_i}.
\]
Higher order generalized derivatives

If \( f, g \in L^{1,\text{loc}}(\Omega) \) and

\[
\int_{\Omega} g \varphi \, dx = \int_{\Omega} f \frac{\partial^2 \varphi}{\partial x_i \partial x_j} \, dx, \quad \forall \varphi \in \mathcal{C}^2(\Omega),
\]

then \( g \) is a generalized derivative of \( f \) with respect to \( x_i \) and \( x_j \). For generalized derivatives we keep the classical notation and write

\[
g = \frac{\partial^2 f}{\partial x_i \partial x_j} = f_{,ij}.
\]

If \( f \) is differentiable in the classical sense, then its generalized derivatives coincide with the classical ones!
To extend this definition further, we use the multi-index notation and write $D^\alpha f$ in place of $\frac{\partial^k f}{\partial x_1^{\alpha_1} \partial x_2^{\alpha_2} \ldots \partial x_n^{\alpha_n}}$.

**Definition**

Let $f, g \in L^1,\text{loc}(\Omega)$ and

$$\int_{\Omega} g \varphi \, dx = (-1)^{|\alpha|} \int_{\Omega} f D^\alpha \varphi \, dx, \quad \forall \varphi \in \mathcal{C}^k(\Omega).$$

Then, $g$ is called a **generalized derivative** of $f$ of degree

$$|\alpha| := \alpha_1 + \alpha_2 + \ldots + \alpha_n$$

and we write

$$g = D^\alpha f.$$
Sobolev spaces

**Definition**

The spaces of functions that have integrable generalized derivatives up to a certain order are called **Sobolev spaces**. $f \in W^{1,p}(\Omega)$ if $f \in L^p$ and all the generalized derivatives of $f$ of the first order belong to $L^p$, i.e.,

$$f_i = \frac{\partial f}{\partial x_i} \in L^p(\Omega).$$

The norm in $W^{1,p}$ is defined as follows:

$$\|f\|_{1,p,\Omega} := \left( \int_\Omega \left( |f|^p + \sum_{i=1}^n |f_i|^p \right) dx \right)^{1/p}.$$
All the other Sobolev spaces are defined quite similarly: \( f \in W^{k,p}(\Omega) \) if all generalized derivatives up to the order \( k \) are integrable with power \( p \) and the quantity

\[
\|f\|_{k,p,\Omega} := \left( \int_{\Omega} \left| \sum_{\alpha \leq k} D^\alpha f \right|^p \, dx \right)^{1/p}
\]

is finite. For the Sobolev spaces \( W^{k,2}(\Omega) \) we also use a simplified notation \( H^k(\Omega) \).

Sobolev spaces of vector- and tensor-valued functions are introduced by obvious extensions of the above definitions. We denote them by \( W^{k,p}(\Omega, \mathbb{R}^n) \) and \( W^{k,p}(\Omega, \mathbb{M}^{n \times n}) \), respectively.
Embedding Theorems

Relationships between the Sobolev spaces and $L^p(\Omega)$ and $C^k(\Omega)$ are given by **Embedding Theorems**.

If $p, q \geq 1$, $\ell > 0$ and $\ell + \frac{n}{q} \geq \frac{n}{p}$, then $W^{\ell,p}(\Omega)$ is continuously embedded in $L^q(\Omega)$. Moreover, if $\ell + \frac{n}{q} > \frac{n}{p}$, then the embedding operator is compact.

If $\ell - k > \frac{n}{p}$, then $W^{\ell,p}(\Omega)$ is compactly embedded in $C^k(\Omega)$.
Traces

The functions in Sobolev spaces have counterparts on $\partial \Omega$ called \textit{traces}. Thus, there exist some bounded operators mapping the functions defined in $\Omega$ to functions defined on the boundary, e.g.,

$$
\gamma : H^1(\Omega) \rightarrow L^2(\partial \Omega)
$$

is called the \textit{trace operator} if it satisfies the following conditions:

$$
\gamma v = v |_{\partial \Omega}, \quad \forall v \in C^1(\Omega),
$$

$$
\|\gamma v\|_{2, \partial \Omega} \leq c \|v\|_{1,2,\Omega},
$$

where $c$ is a positive constant independent of $v$. From these relations, we observe that such a trace is a natural generalization of the trace defined for a continuous function.
It was established that $\gamma v$ forms a subset of $L^2(\partial\Omega)$, which is the space $H^{1/2}(\partial\Omega)$. The functions from other Sobolev spaces also are known to have traces in Sobolev spaces with fractional indices.

Henceforth, we understand the boundary values of functions in the sense of traces, so that

$$u = \psi \quad \text{on } \partial\Omega$$

means that the trace $\gamma u$ of a function $u$ defined in $\Omega$ coincides with a given function $\psi$ defined on $\partial\Omega$.

All the spaces of functions that have zero traces on the boundary are marked by the symbol $\circ$ (e.g., $W^{1,p}(\Omega)$ and $H^1(\Omega)$).
Inequalities

1. Friederichs-Steklov inequality.

\[ \|w\| \leq C_\Omega \|\nabla w\| , \quad \forall w \in \dot{H}^1(\Omega), \]  

\[ (3) \]

2. Poincaré inequality.

\[ \|w\| \leq \tilde{C}_\Omega \|\nabla w\| , \quad \forall w \in \tilde{H}^1(\Omega), \]  

\[ (4) \]

where \( \tilde{H}^1(\Omega) \) is a subset of \( H^1 \) of functions with zero mean.

\[ \int_\Omega \left( |v|^2 + |\varepsilon(v)|^2 \right) \, dx \geq \mu_\Omega \|v\|_{1,2,\Omega}^2, \quad \forall v \in H^1(\Omega, \mathbb{R}^n), \]  

\[ (5) \]
Generalized solutions

The concept of generalized solutions to PDE’s came from the Petrov-Bubnov-Galerkin method.

\[ \int_{\Omega} (\Delta u + f)w \, dx = 0 \quad \forall w \]

Integration by parts leads to the so–called **generalized formulation** of the problem: find \( u \in H^1(\Omega) + u_0 \) such that

\[ \int_{\Omega} \nabla u \cdot \nabla w \, dx = \int_{\Omega} f w \, dx \quad \forall w \in H^1(\Omega) \]

This idea admits wide extensions to many differential equations, see e.g., O. A. Ladyzhenskaya, *The boundary value problems of mathematical physics*. Springer-Verlag, New York, 1985
Definition

A symmetric form $B : V \times V \rightarrow \mathbb{R}$, where $V$ is a Hilbert space, called $V - \text{elliptic}$ if $\exists c_1 > 0, c_2 > 0$ such that

$$B(u, u) \geq c_1 \|u\|^2, \quad \forall u \in V$$

$$|B(u, v)| \leq c_2 \|u\| \|v\|, \quad \forall u, v \in V$$

General formulation for linear PDE’s is: for a certain linear continuous functional $f$ (from the space $V^*$ topologically dual to $V$) find $u$ such that

$$B(u, w) = \langle f, w \rangle \quad w \in V.$$
Existence of a solution

Usually, existence is proved by

**Lax-Milgram Lemma** For a bilinear form $B$ there exists a linear bounded operator $A \in \mathcal{L}(V, V)$ such that

$$B(u, v) = (Au, v), \ \forall u, v \in V$$

It has an inverse $A^{-1} \in \mathcal{L}(V, V)$, such that $\|A\| \leq c_2$, $\|A^{-1}\| \leq \frac{1}{c_1}$.

We will follow another *modus operandi* !!!.
Variational approach

Lemma

If $J : K \rightarrow \mathbb{R}$ is convex, continuous and coercive, i.e.,

$$J(w) \rightarrow +\infty \quad \text{as} \quad \|w\|_V \rightarrow +\infty$$

and $K$ is a convex closed subset of a reflexive space $V$, then the problem

$$\inf_{w \in K} J(w)$$

has a minimizer $u$. If $J$ is strictly convex, then the minimizer is unique.

Coercivity

Take $J(w) = \frac{1}{2} B(w, w) - <f, w>$ and let $K$ be a certain subspace. Then

$$\frac{1}{2} B(w, w) \geq c_1 \|w\|_V^2, \quad |<f, w>| \leq \|f\|_{V^*} \|w\|_V.$$ 

We see, that

$$J(w) \geq c_1 \|w\|_V^2 - \|f\|_{V^*} \|w\|_V \rightarrow +\infty \quad \text{as} \quad \|w\|_V \rightarrow +\infty$$

Since $J$ is strictly convex and continuous we conclude that a minimizer exists and unique.
Useful algebraic relation

First we present the algebraic identity

\[
\frac{1}{2} B(u - v, u - v) = \frac{1}{2} B(v, v) - \langle f, v \rangle + \\
+ \langle f, u \rangle - \frac{1}{2} B(u, u) - B(u, v - u) + \langle f, v - u \rangle = \\
= J(v) - J(u) - B(u, v - u) + \langle f, v - u \rangle
\]  

(6)

From this identity we derive two important results:

- (a) Minimizer \( u \) satisfies \( B(u, w) = \langle f, w \rangle \; \forall w \);
- (b) Error is subject to the difference of functionals.
Let us show (a), i.e., that from (6) it follows the identity

$$B(u, v - u) = < f, v - u > \quad \forall v \in K,$$

which is $B(u, w) = < f, w >$ if set $w = v - u$. Indeed, assume the opposite, i.e. $\exists \tilde{v} \in K$ such that

$$B(u, \tilde{v} - u) - < f, \tilde{v} - u > = \delta > 0 \quad (\tilde{v} \neq u!)$$

Set $\tilde{v} := u + \alpha(\tilde{v} - u), \alpha \in \mathbb{R}$. Then $\tilde{v} - u = \alpha(\tilde{v} - u)$ and

$$\frac{1}{2}B(u - \tilde{v}, u - \tilde{v}) + B(u, \tilde{v} - u) - < f, \tilde{v} - u > =$$

$$= \frac{\alpha^2}{2}B(\tilde{v} - u, \tilde{v} - u) + \alpha\delta = J(\tilde{v}) - J(u) \geq 0$$

However, for arbitrary $\alpha$ such an inequality cannot be true. Denote $a = B(\tilde{v} - u, \tilde{v} - u)$. Then in the left–hand side we have a function

$$\frac{1}{2}\alpha^2 a^2 + \alpha\delta,$$

which always attains negative values for certain $\alpha$. For example, set $\alpha = -\delta/a^2$. Then, the left–hand side is equal to $-\frac{1}{2}\delta^2/a^2 < 0$ and we arrive at a contradiction.
A priori approach to the error control problem
Error estimate

Now, we show (b). From

$$\frac{1}{2} B(u - v, u - v) =$$

$$= J(v) - J(u) - B(u, v - u) + < f, v - u >$$

we obtain the error estimate:

$$\frac{1}{2} B(u - v, u - v) = J(v) - J(u).$$ \hspace{1cm} (7)

which immediately gives the projection estimate
Projection estimate

Let $u_h$ be a minimizer of $J$ on $K_h \subset K$. Then

$$\frac{1}{2} B(u - u_h, u - u_h) = J(u_h) - J(u) \leq J(v_h) - J(u) =$$

$$= \frac{1}{2} B(u - v_h, u - v_h) \quad \forall v_h \in K_h.$$

and we observe that

$$B(u - u_h, u - u_h) = \inf_{v_h \in K_h} B(u - v_h, u - v_h) \quad (8)$$

Projection type estimates serve a basis for deriving a priori convergence estimates.
Interpolation in Sobolev spaces

Two key points: PROJECTION ESTIMATE and INTERPOLATION IN SOBOLEV SPACES. Interpolation theory investigates the difference between a function in a Sobolev space and its piecewise polynomial interpolant. Basic estimate on a simplex $T_h$ is

$$|v - \Pi_h v|_{m,t,T_h} \leq C(m, n, t) \left( \frac{h}{\rho} \right)^m h^{2-m} \|v\|_{2,t,T_h},$$

and on the whole domain

$$|v - \Pi_h v|_{m,t,\Omega_h} \leq Ch^{2-m} \|v\|_{2,t,\Omega_h}.$$

Here $h$ is a the element size and $\rho$ is the inscribed ball diameter.
Asymptotic convergence estimates

Typical case is \( m = 1 \) and \( t = 2 \). Since

\[
B(u - u_h, u - u_h) \leq B(u - \Pi_h u, u - \Pi_h u) \leq c_2 \| u - \Pi_h u \|^2
\]

for

\[
B(w, w) = \int_{\Omega} \nabla w \cdot \nabla w \, dx
\]

we find that

\[
\| \nabla (u - u_h) \| \leq Ch|u|_{2,\Omega}.
\]

provided that

- Exact solution is \( H^2 \) – regular;
- \( u_h \) is the Galerkin approximation;
- Elements do not ”degenerate” in the refinement process.
A priori convergence estimates cannot guarantee that the error monotonically decreases as $h \to 0$.
Besides, in practice we are interested in the error of a concrete approximation on a particular mesh. Asymptotic estimates could hardly be helpful in such a context because, in general, the constant $C$ serves for the whole class of approximate solutions of a particular type. Typically it is either unknown or highly overestimated.

A priori convergence estimates have mainly a theoretical value: they show that an approximation method is correct "in principle."
For these reasons, a quite different approach to error control is rapidly developing. Nowadays it has already formed a new direction: A Posteriori Error Control for PDE's.
A posteriori error estimation methods developed in 1900-1975
Runge’s rule

At the end of 19th century a heuristic error control method was suggested by C. Runge who investigated numerical integration methods for ordinary differential equations.
Heuristic rule of C. Runge

If the difference between two approximate solutions computed on a coarse mesh \( \mathcal{T}_h \) with mesh size \( h \) and refined mesh \( \mathcal{T}_{h_{\text{ref}}} \) with mesh size \( h_{\text{ref}} \) (e.g., \( h_{\text{ref}} = h/2 \)) has become small, then both \( u_{h_{\text{ref}}} \) and \( u_h \) are probably close to the exact solution.

In other words, this rule can be formulated as follows:

If \( [u_h - u_{h_{\text{ref}}}] \) is small then \( u_{h_{\text{ref}}} \) is close to \( u \)

where \([ \cdot ]\) is a certain functional or mesh-dependent norm.

Also, the quantity \( [u_h - u_{h_{\text{ref}}}] \) can be viewed (in terms of modern terminology) as a certain a posteriori error indicator.
Runge’s heuristic rule is simple and was easily accepted by numerical analysts.

However, if we do not properly define the quantity \([ \cdot ]\), for which \([u_h - u_{h,\text{ref}}]\) is small, then the such a principle may be not true.

One can present numerous examples where two subsequent elements of an approximation sequence are close to each other, but far from a certain joint limit. For example, such cases often arise in the minimization (maximization) of functionals with ”saturation” type behavior or with a ”sharp–well” structure. Also, the rule may lead to a wrong presentation if, e.g., the refinement has not been properly done, so that new trial functions were added only in subdomains where an approximation is almost coincide with the true solution. Then two subsequent approximations may be very close, but at the same time not close to the exact solution.
Also, in practice, we need to now precisely what the word "close" means, i.e. we need to have a more concrete presentation on the error. For example, it would be useful to establish the following rule:

\[
\text{If } [u_h - u_{\text{ref}}] \leq \varepsilon \text{ then } \|u_h - u\| \leq \delta(\varepsilon),
\]

where the function \( \delta(\varepsilon) \) is known and computable.

In subsequent lectures we will see that for a wide class of boundary–value problems it is indeed possible to derive such type generalizations of the Runge’s rule.
Prager and Synge estimates

Prager and Synge derived an estimate on the basis of purely geometrical grounds. In modern terms, there result for the problem

\[ \Delta u + f = 0, \quad \text{in } \Omega, \]
\[ u = 0, \quad \text{on } \partial \Omega \]

reads as follows:

\[ \| \nabla (u - v) \|^2 + \| \nabla u - \tau \|^2 = \| \nabla v - \tau \|^2, \]

where \( \tau \) is a function satisfying the equation \( \text{div} \tau + f = 0 \).
We can easily prove it by the orthogonality relation

\[ \int_{\Omega} \nabla (u - v) \cdot (\nabla u - \tau) \, dx = 0 \quad \text{ (div}(\nabla u - \tau) = 0!). \]
Estimate of Mikhlin

A similar estimate was derived by variational arguments (see Lecture 1). It is as follows:

\[
\frac{1}{2} \| \nabla (u - v) \|^2 \leq J(v) - \inf J,
\]

where

\[
J(v) := \frac{1}{2} \| \nabla v \|^2 - (f, v), \quad \inf J := \inf_{v \in H_1(\Omega)} J(v).
\]
Dual problem

Since

\[ \inf J = \sup_{\tau \in Q_f} \left\{ -\frac{1}{2} \| \tau \|^2 \right\}, \]

where

\[ Q_f := \left\{ \tau \in L^2(\Omega, \mathbb{R}^d) \mid \int_{\Omega} \tau \cdot \nabla w \, dx = \int_{\Omega} fw \, dx \quad \forall w \in H^1 \right\}, \]

we find that

\[ \frac{1}{2} \| \nabla (u - v) \|^2 \leq J(v) + \frac{1}{2} \| \tau \|^2, \quad \forall \tau \in Q_f. \]
Since

\[ J(v) + \frac{1}{2} \| \tau \|^2 = \frac{1}{2} \| \nabla v \|^2 - \int_{\Omega} f v \, dx + \frac{1}{2} \| \tau \|^2 = \]

\[ = \frac{1}{2} \| \nabla v \|^2 - \int_{\Omega} \tau \cdot \nabla v \, dx + \frac{1}{2} \| \tau \|^2 = \]

\[ = \frac{1}{2} \| \nabla v - \tau \|^2 \]

we arrive at the estimate

\[ \frac{1}{2} \| \nabla (u - v) \|^2 \leq \frac{1}{2} \| \nabla v - \tau \|^2, \quad \forall \tau \in Q_f. \]  

(9)
Estimates of Prager and Synge and of Mikhlin are valid for any \( \mathbf{v} \in H_1(\Omega) \), so that, formally, that they can be applied to any conforming approximation of the problem. However, from the practical viewpoint these estimates have an essential drawback:

\[
\text{they use a function } \tau \text{ in the set } Q_f \text{ defined by the differential relation,}
\]

which may be difficult to satisfy exactly. Probably by this reason further development of a posteriori error estimates for Finite Element Methods (especially in 80’-90’) was mainly based on different grounds.
Consider a Banach space \((X, d)\) and a continuous operator
\[ \mathcal{T} : X \to X. \]

**Definition**

A point \(x_\circ\) is called a fixed point of \(\mathcal{T}\) if
\[ x_\circ = \mathcal{T} x_\circ. \]  
(10)

Approximations of a fixed point are usually constructed by the iteration sequence
\[ x_i = \mathcal{T} x_{i-1} \quad i = 1, 2, \ldots. \]  
(11)
Contractive mappings

Two basic tasks:

(a) find the conditions that guarantee convergence of $x_i$ to $x_\circ$,
(b) find computable estimates of the error $e_i = d(x_i, x_\circ)$.

Definition

An operator $\mathcal{T} : X \to X$ is called $q$-contractive on a set $S \subset X$ if there exists a positive real number $q$ such that the inequality

$$d(\mathcal{T}x, \mathcal{T}y) \leq q d(x, y)$$

holds for any elements $x$ and $y$ of the set $S$. 

(12)
Theorem (S. Banach)

Let $\mathcal{F}$ be a $q$-contractive mapping of a closed nonempty set $S \subset X$ to itself with $q < 1$. Then, $\mathcal{F}$ has a unique fixed point in $S$ and the sequence $x_i$ obtained by (11) converges to this point.
\textbf{Proof.} It is easy to see that
\begin{align*}
    d(x_{i+1}, x_i) &= d(\mathcal{T}_x, \mathcal{T}_x_{i-1}) \leq q d(x_i, x_{i-1}) \leq \ldots \leq q^i d(x_1, x_0).
\end{align*}
Therefore, for any $m > 1$ we have
\begin{align*}
    d(x_{i+m}, x_i) &\leq d(x_{i+m}, x_{i+m-1}) + d(x_{i+m-1}, x_{i+m-2}) + \ldots + d(x_{i+1}, x_i) \\
    &\leq q^i(q^{m-1} + q^{m-2} + \ldots + 1)d(x_1, x_0). \quad (13)
\end{align*}
Since

\[ \sum_{k=0}^{m-1} q^k \leq \frac{1}{1 - q}, \]

(13) implies the estimate

\[ d(x_{i+m}, x_i) \leq \frac{q^i}{1 - q} d(x_1, x_0). \] \hspace{1cm} (14)

Let \( i \to \infty \), then the right-hand side of (14) tends to zero, so that \( \{x_i\} \) is a Cauchy sequence. It has a limit in \( y \in X \).
Then, \( d(x_i, y) \to 0 \) and

\[
d(Tx_i, Ty) \leq qd(x_i, y) \to 0
\]

so that \( d(Tx_i, Ty) \to 0 \) and \( Tx_i \to Ty \). Pass to the limit in (11) as \( i \to +\infty \). We observe that

\[
Ty = y.
\]

Hence, any limit of such a sequence is a fixed point.
It is easy to prove that a fixed point is unique. Assume that there are two different fixed points \( x_1 \) and \( x_2 \), i.e.

\[
\mathcal{T}x_k = x_k, \quad k = 1, 2.
\]

Therefore,

\[
d(x_1, x_2) = d(\mathcal{T}x_1, \mathcal{T}x_2) \leq qd(x_1, x_2).
\]

But \( q < 1 \), and thus such an inequality cannot be true.
A priori convergence estimate

Let $e_j = d(x_j, x_0)$ denote the error on the $j$-th step. Then

$$e_j = d(\Xi x_{j-1}, \Xi x_0) \leq qe_{j-1} \leq q^j e_0.$$ 

and

$$e_j \leq q^j e_0. \quad (15)$$

This estimate gives a certain presentation on how the error decreases. However, this a priori upper bound may be rather coarse.
The proposition below furnishes upper and lower estimates of $e_j$, which are easy to compute provided, that the number $q$ (or a good estimate of it) is known.

Theorem (A. Ostrowski)

Let \( \{x_j\}_j^{\infty} \) be a sequence obtained by the iteration process

\[
x_i = \Phi x_{i-1} \quad i = 1, 2, ...
\]

with a mapping \( \Phi \) satisfying the condition \( \|\Phi\| = q \leq 1 \). Then, for any \( x_j \), \( j > 1 \), the following estimate holds:

\[
M_j^\oplus := \frac{1}{1+q} d(x_{j+1}, x_j) \leq e_j \leq M_j^\ominus := \frac{q}{1-q} d(x_j, x_{j-1}). \quad (16)
\]
Proof. The upper estimate in (16) follows from (14). Indeed, put $i = 1$ in this relation. We have

$$d(x_{1+m}, x_1) \leq \frac{q}{1 - q} d(x_1, x_0).$$

Since $x_{1+m} \to x_\circ$ as $m \to +\infty$, we pass to the limit with respect to $m$ and obtain

$$d(x_\circ, x_1) \leq \frac{q}{1 - q} d(x_1, x_0).$$

We may view $x_{j-1}$ as the starting point of the sequence. Then, in the above relation $x_0 = x_{j-1}$ and $x_1 = x_j$ and we arrive at the following upper bound of the error:

$$d(x_\circ, x_j) \leq \frac{q}{1 - q} d(x_j, x_{j-1}).$$
The lower bound of the error follows from the relation
\[ d(x_j, x_{j-1}) \leq d(x_j, x_{\ominus}) + d(x_{j-1}, x_{\ominus}) \leq (1 + q)d(x_{j-1}, x_{\ominus}), \]
which shows that
\[ d(x_{j-1}, x_{\ominus}) \geq \frac{1}{1 + q}d(x_j, x_{j-1}). \]

Note that
\[ \frac{M^j_{\ominus}}{M^i_{\ominus}} = \frac{q(1 + q)}{1 - q} \frac{d(x_j, x_{j-1})}{d(x_{j+1}, x_j)} \geq \frac{1 + q}{1 - q}, \]
we see that that the efficiency of the upper and lower bounds given by (16) deteriorates as \( q \to 1 \).
Remark. If $X$ is a normed space, then

\[ d(x_{j+1}, x_j) = \| R(x_j) \|, \]

where

\[ R(x_j) := \mathcal{T}x_j - x_j \]

is the residual of the basic equation (10). Thus, the upper and lower estimates of errors are expressed in terms of the residuals of the respective iteration equation computed for two neighbor steps:

\[
\frac{1}{1 + q} \| R(x_j) \| \leq e_j = d(x_j, x_0) \leq \frac{q}{1 - q} \| R(x_{j-1}) \|. \]
In the iteration methods, it is often easier to analyze the operator

$$\mathcal{Z} = T^n := \underbrace{TT\ldots T}_n \text{ times}$$

where $T$ is a certain mapping.

**Proposition (1)**

Let $T : S \rightarrow S$ be a continuous mapping such that $\mathcal{Z}$ is a $q$-contractive mapping with $q \in (0, 1)$. Then, the equations

$$x = Tx \quad \text{and} \quad x = \mathcal{Z}x$$

have one and the same fixed point, which is unique and can be found by the above described iteration procedure.
**Proof.** By the Banach Theorem, we observe that the operator $\mathfrak{T}$ has a unique fixed point $\xi_\circ$.
Let us show that $\xi_\circ$ is a fixed point of $T$, we note that

$$T\xi_\circ = T(\mathfrak{T}\xi_\circ) = T\mathfrak{T}^2\xi_\circ = ...$$

$$= T\mathfrak{T}^i\xi_\circ = T^{(1+i\pi)}\xi_\circ = T^{i\pi}T\xi_\circ. \quad (17)$$

Denote $x_0 = T\xi_\circ$. By (17) we conclude that for any $i$

$$T\xi_\circ = \mathfrak{T}^i x_0. \quad (18)$$

Passing to the limit on the right-hand side in (18), we arrive at the relation $T\xi_\circ = \xi_\circ$, which means that $\xi_\circ$ is a fixed point of the operator $T$. 
Let \( \tilde{x}_\circ \) be a fixed point of \( T \). Then,

\[
\tilde{x}_\circ = T^2 \tilde{x}_\circ = \ldots = T^n \tilde{x}_\circ = \Xi \tilde{x}_\circ
\]

and we observe that \( \tilde{x}_\circ \) is a fixed point of \( T \). Since the saddle point of \( \Xi \) exists and is unique, we conclude that

\[
x_\circ = \tilde{x}_\circ.
\]

**Remark.** This assertion may be practically useful if it is not possible to prove that \( T \) is \( q \)-contractive, but this fact can be established for a certain power of \( T \).
Iteration methods for bounded linear operators

Consider a bounded linear operator $\mathcal{L} : X \to X$, where $X$ is a Banach space. Given $b \in X$, the iteration process is defined by the relation

$$x_j = \mathcal{L} x_{j-1} + b.$$  \hfill (19)

Let $x_\odot$ be a fixed point of (19) and

$$\|\mathcal{L}\| = q < 1.$$
By applying the Banach Theorem it is easy to show that
\[ \{x_j\} \rightarrow x_\odot. \]

Indeed, let \( \tilde{x}_j = x_j - x_\odot. \) Then
\[ \tilde{x}_j = \mathcal{L}x_{j-1} + b - x_\odot = \mathcal{L}(x_{j-1} - x_\odot) = \mathcal{L}\tilde{x}_{j-1}. \quad (20) \]

Since
\[ 0_x = \mathcal{L}0_x, \]
we note that the zero element \( 0_x \) is a unique fixed point of the operator \( \mathcal{L}. \)
By the Banach theorem \( \tilde{x}_j \rightarrow 0_x \) and, therefore, \( \{x_j\} \rightarrow x_\odot. \)
Therefore, we have an *a priori* estimate

$$
\|x_j - x_\odot\|_X = \|\bar{x}_j - 0_x\|_X \leq \frac{q_j}{1 - q} \|\bar{x}_1 - \bar{x}_0\|_X = \frac{q_j}{1 - q} \|R(x_0)\|_X \quad (21)
$$

and the *a posteriori* one

$$
\|x_j - x_\odot\|_X \leq \frac{q}{1 - q} \|R(x_j-1)\|_X, \quad (22)
$$

where $R(z) = Lz + b - z$ is the residual of the functional equation considered.
By applying the general theory, we also obtain a lower bound of the error

\[ \|x_j - x_\circ\|_X \geq \frac{1}{1 + q} \|x_{j+1} - x_j\|_X = \frac{1}{1 + q} \|R(x_j)\|_X. \]  

(23)

Hence, we arrive at the following estimates for the error in the linear operator equation:

\[ \frac{1 - q}{q} \|x_j - x_\circ\|_X \leq \|R(x_{j-1})\|_X \leq (1 + q) \|x_{j-1} - x_\circ\|_X. \]
Iteration methods in linear algebra

Important applications of the above results are associated with systems of linear simultaneous equations and other algebraic problems. Set $X = \mathbb{R}^n$ and assume that $\mathcal{L}$ is defined by a nondegenerate matrix $A \in \mathbb{M}_{n \times n}$ decomposed into three matrixes

$$A = A_\ell + A_d + A_r,$$

where $A_\ell$, $A_r$, and $A_d$ are certain lower, upper, and diagonal matrices, respectively.
Iteration methods for systems of linear simultaneous equations associated with $A$ are often represented in the form

$$B \frac{x_i - x_{i-1}}{\tau} + A x_{i-1} = f.$$  (24)

In (24), the matrix $B$ and the parameter $\tau$ may be taken in various ways (depending on the properties of $A$). We consider three frequently encountered cases:

(a) $B = A_d$, 

(b) $B = A_d + A_\ell$, 

(c) $B = A_d + \omega A_\ell$, $\tau = \omega$.

For $\tau = 1$, (a) and (b) lead to the methods of Jacobi and Zeidel, respectively. In (c), the parameter $\omega$ must be in the interval $(0, 2)$. If $\omega > 1$, we have the so-called ”upper relaxation method”, and $\omega < 1$ corresponds to the ”lower relaxation method”.
The method (24) is reduced to (19) if we set

\[ \mathcal{L} = \mathbb{I} - \tau B^{-1}A \quad \text{and} \quad b = \tau B^{-1}f, \quad (25) \]

where \( \mathbb{I} \) is the unit matrix. It is known that \( x_i \) converges to \( x_\odot \) that is a solution of the system

\[ Ax_\odot = f \quad (26) \]

if an only if all the eigenvalues of \( \mathcal{L} \) are less than one.

Obviously, \( B \) and \( \tau \) should be taken in such a way that they guarantee the fulfillment of this condition.
Assume that $\|\mathcal{L}\| \leq q < 1$. In view of (21)-(23), the quantities

\begin{align*}
M_{\oplus}^i &= q(1 - q)^{-1} \|R(x_{i-1})\|, \\
M_{\ominus}^0 &= q^i(1 - q)^{-1} \|R(x_0)\|, \\
M_{\ominus}^i &= (1 + q)^{-1} \|R(x_i)\|
\end{align*}

(27) \quad (28) \quad (29)

furnish upper and lower bounds of the error for the vector $x_i$. 
Remark. It is worth noting that from the practical viewpoint finding an upper bound for $\|L\|$ and proving that it is less than 1 presents a special and often not easy task.

If $q$ is very close to 1, then the convergence of an iteration process may be very slow. As we have seen, in this case, the quality of error estimates is also degraded. A well–accepted way for accelerating the convergence consists of using a modified system obtained from the original one by means of a suitable preconditioner.
Consider the problem

$$Ax = f$$

for a symmetric matrix $A$ with coefficients

$$a_{ij} = \frac{\kappa}{ij} \quad \text{if } i \neq j, \quad \kappa = 0.1$$

$$a_{ii} = i.$$

Solved the system by the iteration method

$$x_{i+1} = (I - \tau B^{-1}A)x_i + \tau B^{-1}F$$

with $B = A_D$ and $x_0 = \{0, 0, \ldots 0\}$, determine $q$ and define two-sided error bounds.
Applications to integral equations

Many problems in science and engineering can be stated in terms of integral equations. One of the most typical cases is to find a function $x \otimes (t) \in C[a, b]$ such that

$$x \otimes (t) = \lambda \int_a^b K(t, s) x \otimes (s) \, ds + f(t),$$

where $\lambda \geq 0$, $K$ (the kernel) is a continuous function for $(x, t) \in Q := \{a \leq s \leq b, \ a \leq t \leq b\}$ and

$$|K(t, s)| \leq M, \quad \forall (t, s) \in Q.$$

Also, we assume that $f \in C[a, b]$. 

Mat-5.210 Special Course in Computational Mechanics, Autumn 2006, S. Repin

Helsinki University of Technology
Let us define the operator $\mathcal{T}$ as follows:

$$y(t) := \mathcal{T}x(t) := \lambda \int_a^b K(t, x) x(s) \, ds + f(t)$$  \hspace{1cm} (31)$$

and show that $\mathcal{T}$ maps continuous functions to continuous ones. Let $t_0$ and $t_0 + \Delta t$ belong to $[a, b]$. Then,

$$|y(t_0 + \Delta t) - y(t_0)| \leq |\lambda| \int_a^b |K(t_0 + \Delta t, s) - K(t_0, s)||x(s)|| \, ds +$$

$$+ |f(t_0 + \Delta t) - f(t_0)|.$$

Since $K$ and $f$ are continuous on the compact sets $Q$ and $[a, b]$, respectively, they are uniformly continuous on these sets.
Therefore, for any given $\varepsilon$ one can find a small number $\delta$ such that

$$|f(t_0 + \Delta t) - f(t_0)| < \varepsilon$$

and

$$|K(t_0 + \Delta t, s) - K(t_0, s)| < \varepsilon,$$

provided that $|\Delta t| < \delta$.

Thus, we have

$$|y(t_0 + \Delta t) - y(t_0)| \leq \varepsilon(\|b - a\| \max_{s \in [a,b]} |x(s)| + 1) = C\varepsilon,$$

and, consequently, $y(t_0 + \Delta t)$ tends to $y(t_0)$ as $|\Delta t| \to 0$. 
\( \mathcal{T} : C[a, b] \to C[a, b] \) is a **contractive mapping**. Indeed,

\[
d(\mathcal{T}x, \mathcal{T}y) = \max_{a \leq t \leq b} |\mathcal{T}x(t) - \mathcal{T}y(t)| =
\]

\[
\leq \max_{a \leq t \leq b} \left| \lambda \int_a^b K(t, s) (x(s) - y(s)) \, ds \right| \leq \\
\leq |\lambda| M(b - a) \max_{a \leq s \leq b} |x(s) - y(s)| = |\lambda| M(b - a) d(x, y),
\]

so that \( \mathcal{T} \) is a \( q \)-contractive operator with

\[
q = |\lambda| M(b - a), \quad (32)
\]

provided that

\[
|\lambda| < \frac{1}{M(b - a)}. \quad (33)
\]
Numerical procedure

An approximate solution of (30) can be found by the iteration method

\[ x_{i+1}(t) = \lambda \int_{a}^{b} K(t, s)x_i(s) \, ds + f(t). \]  (34)

If (33) holds, then from the Banach theorem it follows that the sequence \( \{x_i\} \) converges to the exact solution.

We apply the theory exposed above and find that the accuracy of \( x_i \) is subject to the estimate

\[
\frac{1}{1+q} \int_{a}^{b} K(t, s)(x_{i+1}(s) - x_i(s)) \, ds \leq \\
\leq \max_{a \leq t \leq b} |x_i(t) - x_\circ(t)| \leq \frac{q}{1-q} \int_{a}^{b} K(t, s)(x_i(s) - x_{i-1}(s)) \, ds. \]  (35)
Applications to Volterra type equations

Consider the fixed point problem

\[ x_\circ(t) = \lambda \int_a^t K(t, s) x_\circ(s) \, ds + f(t), \]  

(36)

where

\[ |K(t, s)| \leq M, \quad \forall (t, s) \in Q \]

and \( f \in C[a, b] \).

Define the operator \( T \) as follows:

\[ Tx(t) = \lambda \int_a^t K(t, s) x(s) \, ds + f(t). \]

Similarly, to the previous case we establish that

\[ d(Tx, Ty) \leq |\lambda|M(t - a)d(x, y). \]
By the same arguments we find that
\[ d(T^n x, T^n y) \leq |\lambda|^n M^n \frac{(t - a)^n}{n!} d(x, y), \]

Thus, the operator \( \mathcal{T} := T^n \) is \( q \)-contractive with a certain \( q < 1 \), provided that \( n \) is large enough.

In view of Proposition 1, we conclude that the iteration method converges to \( x_0 \) and the errors are controlled by the two–sided error estimates.
Applications to ordinary differential equations

Let \( u \) be a solution of the simplest initial boundary-value problem

\[
\frac{du}{dt} = \varphi(t, u(t)), \quad u(t_0) = a,
\]  \hspace{1cm} (37)

where the solution \( u(t) \) is to be found on the interval \([t_0, t_1]\). Assume that the function \( \varphi(t, p) \) is continuous on the set

\[
Q = \{t_0 \leq t \leq t_1, \ a - \Delta \leq p \leq a + \Delta\}
\]

and

\[
|\varphi(t, p_1) - \varphi(t, p_2)| \leq L|p_1 - p_2|, \quad \forall (t, p) \in Q. \hspace{1cm} (38)
\]
Problem (37) can be reduced to the integral equation

$$u(t) = \int_{t_0}^{t} \varphi(s, u(s)) \, ds + a$$

(39)

and it is natural to solve the latter problem by the iteration method

$$u_j(t) = \int_{t_0}^{t} \varphi(s, u_{j-1}(s)) \, ds + a.$$

(40)

To justify this procedure, we must verify that the operator

$$\mathfrak{T}u := \int_{t_0}^{t} \varphi(s, u(s)) \, ds + a$$

is q-contractive with respect to the norm

$$\|u\| := \max_{t \in [t_0, t_1]} |u(t)|.$$

(41)
We have

\[ \left\| \mathcal{T}z - \mathcal{T}y \right\| = \max_{t \in [t_0, t_1]} \left| \int_{t_0}^{t} (\varphi(s, z(s)) - \varphi(s, y(s))) \, ds \right| \leq \]

\[ \leq \max_{t \in [t_0, t_1]} L \int_{t_0}^{t} |z(s) - y(s)| \, ds \leq L \int_{t_0}^{t_1} |z(s) - y(s)| \, ds \leq \]

\[ \leq L(t_1 - t_0) \max_{s \in [t_0, t_1]} |z(s) - y(s)| = L(t_1 - t_0) \|z - y\|. \]

We see that if

\[ t_1 < t_0 + L^{-1}, \] (42)

then the operator \( \mathcal{T} \) is \( q \)-contractive with

\[ q := L(t_1 - t_0) < 1. \]
Therefore, if the interval \([t_0, t_1]\) is small enough (i.e., it satisfies the condition [42]), then the existence and uniqueness of a continuous solution \(u(t)\) follows from the Banach theorem. In this case, the solution can be found by the iteration procedure whose accuracy is explicitly controlled by the two–sided error estimates.

For a more detailed investigation of the fixed point methods for integral and differential equations see

A posteriori estimates based on monotonicity.

The theory of monotone operators gives another way of constructing a posteriori estimates.

Monotone operators are defined on the so-called ordered (or partially ordered) spaces that introduce the relation $x \leq y$ for all (or almost all) elements $x, y$ of the space.

**Definition**

An operator $\mathcal{T}$ is called monotone if $x \leq y$ implies $\mathcal{T}x \leq \mathcal{T}y$. 
Consider the fixed point problem
\[ x_\circ = \mathcal{T}x_\circ + f \]
on an ordered (partially ordered) space \( X \). Assume that
\[ \mathcal{T} = \mathcal{T}_\oplus + \mathcal{T}_\ominus, \]
\( \mathcal{T}_\oplus \) is monotone,
\( \mathcal{T}_\ominus \) is antitone: \( x \leq y \) implies \( \mathcal{T}x \geq \mathcal{T}y \),
\( \mathcal{T}_\oplus \) and \( \mathcal{T}_\ominus \) have a common set of images \( D \) which is a convex subset of \( X \).
Next, let \( x_\ominus 0, x_\ominus 1, x_\oplus 0, x_\oplus 1 \in D \) be such elements that

\[
x_\ominus 0 \leq x_\ominus 1 \leq x_\oplus 1 \leq x_\oplus 0,
\]

\[
x_\ominus 1 = \mathcal{T} \oplus x_\ominus 0 + \mathcal{T} \ominus x_\oplus 0 + f,
\]

\[
x_\oplus 1 = \mathcal{T} \oplus x_\ominus 0 + \mathcal{T} \ominus x_\oplus 0 + f,
\]

Then, we observe that

\[
x_\ominus 2 = \mathcal{T} \oplus x_\ominus 1 + \mathcal{T} \ominus x_\oplus 1 + f \geq \mathcal{T} \oplus x_\ominus 0 + \mathcal{T} \ominus x_\oplus 0 + f = x_\ominus 1
\]

\[
x_\oplus 2 = \mathcal{T} \oplus x_\ominus 1 + \mathcal{T} \ominus x_\oplus 1 + f \leq \mathcal{T} \oplus x_\ominus 0 + \mathcal{T} \ominus x_\oplus 0 + f = x_\oplus 1.
\]
By continuing the iterations we obtain elements such that

\[ x \ominus k \leq x \ominus (k+1) \leq x \oplus (k+1) \leq x \oplus k. \]

Then \( x \rightarrow \mathcal{T}x + f \) maps \( D \) to itself. If \( D \) is compact, then by the Schauder fixed point theorem \( x_\odot \in D \) exists. Moreover, it is bounded from below and above by the sequences \( \{x \ominus k\} \) and \( \{x \oplus k\} \).
Applications of this method are mainly oriented towards systems of linear simultaneous equations and integral equations (see L. Collatz. Funktionanalysis und numerische mathematik, Springer-Verlag, Berlin, 1964). For example, consider a system of linear simultaneous equations

\[ x = Ax + f \]

that is supposed to have a unique solution \( x_\circ \). Assume that

\[
A = A_\oplus - A_\ominus, \quad A_\ominus = \{a_{ij}^\ominus\} \in \mathbb{M}^{n \times n}, \\
A_\oplus = \{a_{ij}^\oplus\} \in \mathbb{M}^{n \times n}, \quad a_{ij}^\ominus \geq 0, \quad a_{ij}^\oplus \geq 0.
\]

We may partially order the space \( \mathbb{R}^n \) by saying that \( x \leq y \) if and only if \( x_i \leq y_i \) for \( i = 1, 2, \ldots n \). Compute the vectors

\[
x_\ominus(k+1) = A_\ominus x_\ominus k + A_\ominus x_\ominus k + f, \quad x_\oplus(k+1) = A_\oplus x_\oplus k + A_\ominus x_\ominus k + f.
\]

If \( x_\ominus 0 \leq x_\ominus 1 \leq x_\circ \leq x_\oplus 1 \leq x_\oplus 0 \), then for all the components of \( x_\circ \) we obtain two–sided estimates

\[
x_{\ominus k}^{(i)} \leq x_{\ominus (k+1)}^{(i)} \leq x_{\circ}^{(i)} \leq x_{\oplus (k+1)}^{(i)} \leq x_{\oplus k}^{(i)}, \quad i = 1, 2, \ldots n.
\]
Task 3.

Apply the above method for finding two–sided bounds of the Euclid error norm and componentwise errors for a system of linear simultaneous equations

$$A x = f$$

where

$$a_{ij} = (-1)^{i+j} \kappa / ij \quad \text{if } i \neq j, \quad \kappa = 0.1$$

$$a_{ii} = i.$$ 

For the $i$th component of the solution determine the lower and upper bounds as follows:

$$\max_{j=0,1,\ldots,k+1} \left( x_j^{\oplus} \right)_i \leq (x_\otimes)_i \leq \min_{j=0,1,\ldots,k+1} \left( x_j^{\ominus} \right)_i.$$
It should be remarked that convergence of $x^{(i)}_\ominus k$ and $x^{(i)}_\oplus k$ to $x_\odot$ (and the convergence rate) requires a special investigation, which must use specific features of a particular problem.

**In principle, a posteriori error estimates based on monotonicity can provide the most informative POINTWISE a posteriori error estimates.** Regrettably, the respective theory has not been yet properly investigated.
The goal of Lecture 2 to give an overview of a posteriori error estimation methods developed for Finite Element approximations in 70th–80th.

Sobolev spaces with negative indices

Definition

Linear functionals defined on the functions of the space \( \dot{C}^{\infty}(\Omega) \) are called distributions. They form the space \( \mathcal{D}'(\Omega) \).

Value of a distribution \( g \) on a function \( \varphi \) is \( \langle g, \varphi \rangle \).

Distributions possess an important property:

they have derivatives of any order

Let \( g \in \mathcal{D}'(\Omega) \), then the quantity \( -\langle g, \frac{\partial \varphi}{\partial x_i} \rangle \) is another linear functional on \( \mathcal{D}(\Omega) \). It is viewed as a generalized partial derivative of \( g \) taken over the \( i \)-th variable.
Derivatives of $L^q$–functions

Any function $g$ from the space $L^q(\Omega)$ ($q \geq 1$) defines a certain distribution as

$$\langle g, \varphi \rangle = \int_{\Omega} g \varphi \, dx$$

and, therefore, has generalized derivatives of any order. The sets of distributions, which are derivatives of $q$-integrable functions, are called Sobolev spaces with negative indices.
Definition

The space $W^{-\ell, q}(\Omega)$ is the space of distributions $g \in \mathcal{D}'(\Omega)$ such that

$$g = \sum_{|\alpha| \leq \ell} D^\alpha g_\alpha,$$

where $g_\alpha \in L^q(\Omega)$. 
Spaces $W^{-1,p}(\Omega)$

$W^{-1,p}(\Omega)$ contains distributions that can be viewed as generalized derivatives of $L^q$-functions. The functional

$$\left\langle \frac{\partial f}{\partial x_i}, \varphi \right\rangle := - \int_{\Omega} f \frac{\partial \varphi}{\partial x_i} \, dx \quad f \in L^q(\Omega)$$

is linear and continuous not only for $\varphi \in \hat{C}^\infty(\Omega)$ but, also, for $\varphi \in \hat{W}^{1,p}(\Omega)$, where $1/p + 1/q = 1$ (density property). Hence, first generalized derivatives of $f$ lie in the space dual to $\hat{W}^{1,p}(\Omega)$ denoted by $W^{-1,p}(\Omega)$.

For $\hat{W}^{1,2}(\Omega) = \hat{H}^1(\Omega)$, the respective dual space is denoted by $H^{-1}(\Omega)$. 
Norms in "negative spaces"

For $g \in H^{-1}(\Omega)$ we may introduce two equivalent ”negative norms”.

$$\|g\|_{(-1),\Omega} := \sup_{\varphi \in \overset{\circ}{H^1}(\Omega)} \frac{\langle g, \varphi \rangle}{\|\varphi\|_{1,2,\Omega}} < +\infty$$

$$\|g\|_{\Omega} := \sup_{\varphi \in \overset{\circ}{H^1}(\Omega)} \frac{\langle g, \varphi \rangle}{\|
abla \varphi\|_{\Omega}} < +\infty$$

From the definitions, it follows that

$$\langle g, \varphi \rangle \leq \|g\|_{(-1),\Omega} \|\varphi\|_{1,2,\Omega}$$

$$\langle g, \varphi \rangle \leq \|g\|_{\Omega} \|
abla \varphi\|_{\Omega}$$
Errors and Residuals. First glance

If an analyst is not sure in the quality of an approximate solution computed, then the very first idea that comes to his mind is to substitute the approximate solution into the equation and look at the equation residual.
We begin by recalling basic relations between residuals and errors that hold for systems of **linear simultaneous equations**. Let $A \in \mathbb{M}^{n \times n}$, $\det A \neq 0$, consider the system

$$Au + f = 0.$$ 

For any $v$ we have the simplest **residual** type estimate

$$A(v - u) = Av + f; \quad \Rightarrow \quad \|e\| \leq \|A^{-1}\| \|r\|.$$ 

where $e = v - u$ and $r = Av + f$. 
Two–sided estimates

Define the quantities

\[ \lambda_{\text{min}} = \min_{y \in \mathbb{R}^n, y \neq 0} \frac{\| Ay \|}{\| y \|} \quad \text{and} \quad \lambda_{\text{max}} = \max_{y \in \mathbb{R}^n, y \neq 0} \frac{\| Ay \|}{\| y \|} \]

Since \( A e = r \), we see that

\[ \lambda_{\text{min}} \leq \frac{\| Ae \|}{\| e \|} = \frac{\| r \|}{\| e \|} \leq \lambda_{\text{max}} \Rightarrow \lambda_{\text{max}}^{-1} \| r \| \leq \| e \| \leq \lambda_{\text{min}}^{-1} \| r \| . \]

Since \( u \) is a solution, we have

\[ \lambda_{\text{min}} \leq \frac{\| Au \|}{\| u \|} = \frac{\| f \|}{\| u \|} \leq \lambda_{\text{max}} \Rightarrow \lambda_{\text{max}}^{-1} \| f \| \leq \| u \| \leq \lambda_{\text{min}}^{-1} \| f \| . \]

Thus,

\[ \frac{\lambda_{\text{min}}}{\lambda_{\text{max}}} \frac{\| r \|}{\| f \|} \leq \frac{\| e \|}{\| u \|} \leq \frac{\lambda_{\text{max}}}{\lambda_{\text{min}}} \frac{\| r \|}{\| f \|} . \]
Key "residual–error" relation

Since

\[ \frac{\lambda_{\text{max}}}{\lambda_{\text{min}}} = \text{Cond} \, A, \]

we arrive at the basic relation where the matrix condition number serves as an important factor

\[
(\text{Cond} \, A)^{-1} \frac{\|r\|}{\|f\|} \leq \frac{\|e\|}{\|u\|} \leq \text{Cond} \, A \frac{\|r\|}{\|f\|}. \tag{43}
\]

Thus, the relative error is controlled by the relative value of the residual. However, the bounds deteriorate when the conditional number is large.
In principle, the above consideration can be extended to a wider set of linear problems, where

\[ A \in \mathcal{L}(X, Y) \]

is a coercive linear operator acting from a Banach space \( X \) to another space \( Y \) and \( f \) is a given element of \( Y \).

However, if \( A \) is related to a boundary-value problem, then one should properly define the spaces \( X \) and \( Y \) and find a practically meaningful analog of the estimate (43).
Let $\mathcal{A} : X \rightarrow Y$ be a linear elliptic operator. Consider the boundary-value problem

$$\mathcal{A}u + f = 0 \quad \text{in } \Omega, \quad u = u_0 \quad \text{on } \partial \Omega.$$ 

Assume that $v \in X$ is an approximation of $u$. Then, we should measure the error in $X$ and the residual in $Y$, so that the principal form of the estimate is

$$\|v - u\|_X \leq C\|\mathcal{A}v + f\|_Y,$$

where the constant $C$ is independent of $v$. The key question is as follows:

Which spaces $X$ and $Y$ should we choose for a particular boundary-value problem?
Consider the problem

$$\Delta u + f = 0 \quad \text{in} \Omega, \quad u = 0 \quad \text{on} \partial \Omega,$$

with $f \in L^2(\Omega)$. The generalized solution satisfies the relation

$$\int_{\Omega} \nabla u \cdot \nabla w \, dx = \int_{\Omega} fw \, dx \quad \forall w \in V_0 := H^1(\Omega),$$

which implies the energy estimate

$$\|\nabla u\|_{2, \Omega} \leq C_\Omega \|f\|_{2, \Omega}.$$

Here $C_\Omega$ is a constant in the Friederichs-Steklov inequality. Assume that an approximation $v \in V_0$ and $\Delta v \in L^2(\Omega)$. Then,

$$\int_{\Omega} \nabla (u - v) \cdot \nabla w \, dx = \int_{\Omega} (f + \Delta v)w \, dx, \quad \forall w \in V_0.$$
Setting \( w = u - v \), we obtain the estimate

\[ \| \nabla (u - v) \|_{2, \Omega} \leq C_\Omega \| f + \Delta v \|_{2, \Omega}, \tag{45} \]

whose right-hand side of (45) is formed by the \( L^2 \)-norm of the residual. However, usually a sequence of approximations \( \{v_k\} \) converges to \( u \) only in the energy space, i.e.,

\[ \{v_k\} \rightarrow u \quad \text{in} \quad H^1(\Omega), \]

so that \( \| \Delta v_k + f \| \) may not converge to zero!

This means that the \textbf{consistency} (the key property of any practically meaningful estimate) is lost.
Which norm of the residual leads to a consistent estimate of the error in the energy norm?

To find it, we should consider $\Delta$ not as $H^2 \rightarrow L^2$ mapping, but as $H^1 \rightarrow H^{-1}$ mapping. For this purpose we use the integral identity

$$\int_{\Omega} \nabla u \cdot \nabla w \, dx = \langle f, w \rangle, \quad \forall w \in V_0 := \dot{H}^1(\Omega).$$

Here, $\nabla u \in L^2$, so that it has derivatives in $H^{-1}$ and we consider the above as equivalence of two distributions on all trial functions $w \in V_0$.

By $\langle f, w \rangle \leq \| f \| \| \nabla w \|_{2, \Omega}$, we obtain another “energy estimate”

$$\| \nabla u \|_{2, \Omega} \leq \| f \|.$$
Consistent residual estimate

Let $v \in V_0$ be an approximation of $u$. We have

$$
\int_{\Omega} \nabla(u - v) \cdot \nabla w \, dx = \int_{\Omega} (fw - \nabla v \cdot \nabla w) \, dx = \langle \Delta v + f, w \rangle, \quad f + \Delta v \in H^{-1}(\Omega).
$$

By setting $w = v - u$, we obtain

$$
\|\nabla(u - v)\|_{2, \Omega} \leq I f + \Delta v I.
$$

(46)

where

$$
I f + \Delta v I = \sup_{\varphi \in H^1(\Omega)} \frac{|\langle f + \Delta v, \varphi \rangle|}{\|\nabla \varphi\|} = \sup_{\varphi \in H^1(\Omega)} \frac{|\int_{\Omega} \nabla(u - v) \cdot \nabla \varphi|}{\|\nabla \varphi\|} \leq \sup_{\varphi \in H^1(\Omega)} \frac{\|\nabla(u - v)\|}{\|\nabla \varphi\|} \leq \|\nabla(u - v)\|
$$
Thus, for the problem considered

\[ \| \nabla (u - v) \|_{2, \Omega} = f + \Delta v \]

(47)

From (47), it readily follows that

\[ f + \Delta v_k \rightarrow 0 \quad \text{as} \quad \{v_k\} \rightarrow u \quad \text{in} \quad H^1. \]

We observe that the estimate (47) is consistent.
Diffusion equation

Similar estimates can be derived for

\[ Au + f = 0, \quad \text{in } \Omega, \quad u = 0 \text{ on } \partial \Omega, \]

where

\[ Au = \text{div } A \nabla u := \sum_{i,j=1}^{d} \frac{\partial}{\partial x_i} \left( a_{ij}(x) \frac{\partial u}{\partial x_j} \right), \]

\[ a_{ij}(x) = a_{ji}(x) \in L^\infty(\Omega), \]

\[ \lambda_{\min} |\eta|^2 \leq a_{ij}(x) \eta_i \eta_j \leq \lambda_{\max} |\eta|^2, \quad \forall \eta \in \mathbb{R}^n, \ x \in \Omega, \]

\[ \lambda_{\max} \geq \lambda_{\min} \geq 0. \]
Let $v \in V_0$ be an approximation of $u$. Then,

$$\int_{\Omega} A \nabla (u - v) \cdot \nabla w \, dx = \int_{\Omega} (fw - A \nabla v \cdot \nabla w) \, dx, \quad \forall w \in V_0.$$ 

Again, the right-hand side of this relation is a bounded linear functional on $V_0$, i.e.,

$$f + \text{div} (A \nabla v) \in H^{-1}.$$ 

Hence, we have the relation

$$\int_{\Omega} A \nabla (u - v) \cdot \nabla w \, dx = \langle f + \text{div} (A \nabla v), w \rangle, \quad \forall w \in V_0.$$ 

Setting $w = u - v$, we derive the estimate

$$\| \nabla (u - v) \|_{2, \Omega} \leq \lambda_{\text{min}}^{-1} \int f + \text{div} (A \nabla v) \, I.$$  \hspace{1cm} (48)
Next,

\[
\| f + \text{div} (A \nabla v) \| = \sup_{\varphi \in \mathcal{H}^1(\Omega)} \left| \frac{\langle f + \text{div} (A \nabla v), \varphi \rangle}{\| \nabla \varphi \|_{2,\Omega}} \right| = \sup_{\varphi \in \mathcal{H}^1(\Omega)} \left| \int_{\Omega} A \nabla (u - v) \cdot \nabla \varphi \, dx \right| \leq \lambda_{\text{max}} \| \nabla (u - v) \|_{2,\Omega}. \tag{49}
\]

Combining (48) and (49) we obtain

\[
\lambda_{\text{max}}^{-1} \| R(v) \| \leq \| \nabla (u - v) \|_{2,\Omega} \leq \lambda_{\text{min}}^{-1} \| R(v) \|,
\]

where \( R(v) = f + \text{div} (A \nabla v) \in H^{-1}(\Omega) \). We see that upper and lower bounds of the error can be evaluated in terms of the negative norm of \( R(v) \).
Main goal

We observe that to find guaranteed bounds of the error reliable estimates of $|R(v)|$ are required.

In essence, a posteriori error estimates derived in 70-90’ for Finite Element Methods (FEM) offer several approaches to the evaluation of $|R(v)|$. We consider them starting with the so–called explicit residual method where such estimates are obtained with help of two key points:

- Galerkin orthogonality property;
- $H^1 \rightarrow V_h$ interpolation estimates by Clément.
Explicit residual method in 1D case

Take the simplest model

\[(\alpha u')' + f = 0, \quad u(0) = u(1).\]

Let \(I := (0, 1), f \in L^2(I), \alpha(x) \in C(I) \geq \alpha_0 > 0.\) Divide \(I\) into a number of subintervals \(I_i = (x_i, x_{i+1})\), where \(x_0 = 0, x_{N+1} = 1,\) and \(|x_{i+1} - x_i| = h_i.\)

Assume that \(v \in H^1(I)\) and it is smooth on any interval \(I_i.\)

![Diagram of an interval divided into subintervals](image)
In this case,

\[
\int R(v) = \sup_{w \in V_0(I), \ w \neq 0} \frac{\int_0^1 (-\alpha v'w' + fw)dx}{\|w'\|_{2,1}} = \\
= \sup_{w \in H^1(I) : w \neq 0} \frac{\sum_{i=0}^N \int_{l_i} (-\alpha v'w' + fw)dx}{\|w'\|_{2,1}} = \\
= \sup_{w \in V_0(I), \ w \neq 0} \frac{\sum_{i=0}^N \int_{l_i} r_i(v)w \ dx + \sum_{i=1}^N \alpha(x_i)w(x_i)j(v'(x_i))}{\|w'\|_{2,1}},
\]

where \( j(\phi(x)) := \phi(x + 0) - \phi(x - 0) \) is the "jump–function" and 
\( r_i(v) = (\alpha v')' + f \) is the residual on \( l_i \).

For arbitrary \( v \) we can hardly get an upper bound for this supremum.
Use Galerkin orthogonality

Assume that \( v = u_h \), i.e., it is the **Galerkin approximation** obtained on a finite-dimensional subspace \( V_{0h} \) formed by piecewise polynomial continuous functions. Since

\[
\int_I \alpha u'_h w'_h \, dx - \int_I f w_h \, dx = 0 \quad \forall w_h \in V_{0h}.
\]

we may add the left–hand side with any \( w_h \) to the numerator what gives

\[
\lVert R(u_h) \rVert = \sup_{w \in V_0(I)} \frac{\int_0^1 (-\alpha u'_h (w - \pi_h w)' + f(w - \pi_h w)) \, dx}{\lVert w' \rVert_{2,1}},
\]

where \( \pi_h : V_0 \rightarrow V_{0h} \) is the interpolation operator defined by the conditions

\[
\pi_h v \in V_{0h}, \pi_h v(0) = \pi_h v(1) = 0 \quad \text{and}
\]

\[
\pi_h v(x_i) = v(x_i), \quad \forall x_i, \ i = 1, 2, \ldots, N.
\]
Integrating by parts

Now, we have

$$\| R(u_h) \| = \sup_{w \in V_0(I)} \left\{ \frac{\sum_{i=0}^{N} \int_{I_i} r_i(u_h)(w - \pi_h w) \, dx}{\| w' \|_{2,I}} + \sum_{i=1}^{N} \frac{\alpha(x_i)(w(x_i) - \pi_h w(x_i))j(u_h(x_i))}{\| w' \|_{2,I}} \right\}. $$

Since $w(x_i) - \pi_h w(x_i) = 0$, the second sum vanishes. For first one we have

$$\sum_{i=0}^{N} \int_{I_i} r_i(u_h)(w - \pi_h w) \, dx \leq \sum_{i=0}^{N} \| r_i(u_h) \|_{2,I_i} \| w - \pi_h w \|_{2,I_i}.$$
Since for $\mathbf{w} \in H^1(I_i)$

$$\|\mathbf{w} - \pi_h \mathbf{w}\|_{2,I_i} \leq c_i \|\mathbf{w}'\|_{2,I_i},$$

we obtain for the numerator of the above quotient

$$\sum_{i=0}^{N} \int_{I_i} r_i(u_h)(\mathbf{w} - \pi_h \mathbf{w}) \, dx \leq \sum_{i=0}^{N} c_i \|r_i(u_h)\|_{2,I_i} \|\mathbf{w}'\|_{2,I_i} \leq$$

$$\leq \left( \sum_{i=0}^{N} c_i^2 \|r_i(u_h)\|_{2,I_i}^2 \right)^{1/2} \|\mathbf{w}'\|_{2,I_i},$$

which implies the desired upper bound

$$\left| R(u_h) \right| \leq \left( \sum_{i=0}^{N} c_i^2 \|r_i(u_h)\|_{2,I_i}^2 \right)^{1/2}.$$ (51)

This bound is the sum of local residuals $r_i(u_h)$ with weights given by the interpolation constants $c_i$. 
Interpolation constants

For piecewise affine approximations, the interpolation constants \( c_i \) are easy to find. Indeed, let \( \gamma_i \) be a constant that satisfies the condition

\[
\inf_{w \in H^1(I_i)} \frac{\|w\|_{2,I_i}^2}{\|w - \pi_h w\|_{2,I_i}^2} \geq \gamma_i.
\]

Then, for all \( w \in H^1(I_i) \), we have

\[
\|w - \pi_h w\|_{2,I_i} \leq \gamma_i^{-1/2} \|w\|_{2,I_i}^{1/2}
\]

and one can set \( c_i = \gamma_i^{-1/2} \).

Let us estimate \( \gamma_i \).
Note that
\[ \int_{x_i}^{x_{i+1}} |w'|^2 \, dx = \int_{x_i}^{x_{i+1}} |(w - \pi_h w)' + (\pi_h w)'|^2 \, dx, \]
where \((\pi_h w)'\) is constant on \((x_i, x_{i+1})\). Therefore,
\[ \int_{x_i}^{x_{i+1}} (w - \pi_h w)'(\pi_h w)' \, dx = 0 \]
and
\[ \int_{x_i}^{x_{i+1}} |w'|^2 \, dx = \int_{x_i}^{x_{i+1}} |(w - \pi_h w)'|^2 \, dx + \int_{x_i}^{x_{i+1}} |(\pi_h w)'|^2 \, dx \geq \int_{x_i}^{x_{i+1}} |(w - \pi_h w)'|^2 \, dx. \]
Interpolation constants in 1D problem

Thus, we have

\[
\inf_{w \in H^1(l_i)} \frac{\int_{x_i}^{x_{i+1}} |w'|^2 \, dx}{\int_{x_i}^{x_{i+1}} |w - \pi_h w|^2 \, dx} \geq \inf_{w \in \hat{H}^1(l_i)} \frac{\int_{x_i}^{x_{i+1}} |(w - \pi_h w)'|^2 \, dx}{\int_{x_i}^{x_{i+1}} |w - \pi_h w|^2 \, dx} \geq \inf_{\eta \in \hat{H}^1(l_i)} \frac{\int_{x_i}^{x_{i+1}} |\eta'|^2 \, dx}{\int_{x_i}^{x_{i+1}} |\eta|^2 \, dx} = \frac{\pi^2}{h_i^2},
\]

so that \( \gamma_i = \pi^2/h_i^2 \) and \( c_i = h_i/\pi \).

**Remark.** To prove the very last relation we note that

\[
\inf_{\eta \in \hat{H}^1([0,h])} \frac{\int_0^h |\eta'|^2 \, dx}{\int_0^h |\eta|^2 \, dx} = \frac{\pi^2}{h^2}
\]

is attained on the eigenfunction \( \sin \frac{\pi}{h} x \), of the problem \( \phi'' + \lambda \phi = 0 \) on \((0, h)\).
Task 4

Solve a boundary–value problem

\[(\alpha v')' = f,\]
\[v(0) = a, \quad v(1) = b\]

with certain \(\alpha(x) > 0\), \(f\), \(a\), and \(b\) by the finite element method with uniform elements (i.e., \(h = 1/N\)). Apply the residual method and compare the errors computed with the true error distribution.
Residual method in 2D case

Let $\Omega$ be represented as a union $\mathcal{T}_h$ of simplexes $T_i$. For the sake of simplicity, assume that $\overline{\Omega} = \bigcup_{i=1}^{N} \overline{T}_i$ and $V_{0h}$ consists of piecewise affine continuous functions. Then the Galerkin approximation $u_h$ satisfies the relation

$$
\int_{\Omega} A \nabla u_h \cdot \nabla w_h \, dx = \int_{\Omega} f w_h \, dx, \quad \forall w_h \in V_{0h},
$$

where

$$
V_{0h} = \{ w_h \in V_0 \mid w_h \in P^1(T_i), \ T_i \in \mathcal{F}_h \}.
$$
In this case, negative norm of the residual is

$$\| R(u_h) \| = \sup_{w \in V_0} \frac{\int_{\Omega} (f w - A \nabla u_h \cdot \nabla w) \, dx}{\| \nabla w \|_{2,\Omega}}.$$

Let $\pi : \overset{\circ}{H}^1 \rightarrow V_{0h}$ be a continuous interpolation operator. Then, for the Galerkin approximation

$$\| R(u_h) \| = \sup_{w \in V_0} \frac{\int_{\Omega} (f (w - \pi_h w) - A \nabla u_h \cdot \nabla (w - \pi_h w)) \, dx}{\| \nabla w \|_{2,\Omega}}.$$

For finite element approximations such a type projection operators has been constructed. One of the most known was suggested in Ph. Clément. Approximations by finite element functions using local regularization, *RAIRO Anal. Numér.*, 9(1975).

and is often called the **Clement’s interpolation operator**. Its properties play an important role in the a posteriori error estimation method considered.
Clement’s Interpolation operator

Let $E_{ij}$ denote the common edge of the simplexes $T_i$ and $T_j$. If $s$ is an inner node of the triangulation $\mathcal{F}_h$, then $\omega_s$ denotes the set of all simplexes having this node.

For any $s$, we find a polynomial $p_s(x) \in P^1(\omega_s)$ such that

$$\int_{\omega_s} (v - p_s) q \, dx = 0 \quad \forall q \in P^1(\omega_s).$$

Now, the interpolation operator $\pi_h$ is defined by setting

$$\pi_h v(x_s) = p(x_s), \quad \forall x_s \in \Omega,$$

$$\pi_h v(x_s) = 0, \quad \forall x_s \in \partial \Omega.$$

It is a linear and continuous mapping of $H^1(\Omega)$ to the space of piecewise affine continuous functions.
Interpolation estimates in 2D

Moreover, it is subject to the relations

\[ \| \mathbf{v} - \pi_h \mathbf{v} \|_{2,T_i} \leq c_i^T \text{diam}(T_i) \| \mathbf{v} \|_{1,2,\omega_N(T_i)}, \]  
(52)

\[ \| \mathbf{v} - \pi_h \mathbf{v} \|_{2,E_{ij}} \leq c_{ij}^E |E_{ij}|^{1/2} \| \mathbf{v} \|_{1,2,\omega_E(T_i)}, \]  
(53)

where \( \omega_N(T_i) \) is the union of all simplexes having at least one common node with \( T_i \) and \( \omega_E(T_i) \) is the union of all simplexes having a common edge with \( T_i \).

Interpolation constants \( c_i^T \) and \( c_{ij}^E \) are LOCAL and depend on the shape of patches \( \omega_N(T_i) \) and \( \omega_E(T_i) \).
Quotient relations for the constants

Evaluation of $\mathbf{c}_i^T$ and $\mathbf{c}_{ij}^E$ requires finding exact lower bounds of the following variational problems:

$$\gamma_i^T := \inf_{w \in V_0} \frac{\|w\|_{1,2,\omega_N(T_i)}}{\|w - \pi_h w\|_{2,T_i}} \text{diam}(T_i)$$

and

$$\gamma_{ij}^E := \inf_{w \in V_0} \frac{\|w\|_{1,2,\omega_E(T_i)}}{\|w - \pi_h w\|_{2,E_{ij}} |E_{ij}|^{1/2}}.$$

Certainly, we can replace $V_0$ be $H^1(\omega_N(T_i))$ and $H^1(\omega_E(T_i))$, respectively, but, anyway finding the constants amounts solving functional eigenvalue type problems!
Let \( \sigma_h = A \nabla u_h \). Then,

\[
\| R(u_h) \| = \sup_{w \in V_0} \frac{\int_{\Omega} \left( f(w - \pi_h w) - \sigma_h \cdot \nabla (w - \pi_h w) \right) \, dx}{\| \nabla w \|_{2, \Omega}}.
\]

If \( \nu_{ij} \) is the unit outward normal to \( E_{ij} \), then

\[
\int_{T_i} \sigma_h \cdot \nabla (w - \pi_h w) \, dx = \sum_{E_{ij} \subset \partial T_i} \int_{E_{ij}} (\sigma_h \cdot \nu)(w - \pi_h w) \, ds - \int_{T_i} \text{div} \sigma_h (w - \pi_h w) \, dx,
\]

Since on the boundary \( w - \pi_h w = 0 \), we obtain

\[
\| R(u_h) \| = \sup_{w \in V_0} \left\{ \frac{\sum_{i=1}^{N} \int_{T_i} (\text{div} \sigma_h + f)(w - \pi_h w) \, dx}{\| \nabla w \|_{2, \Omega}} + \frac{\sum_{i=1}^{N} \sum_{j>i}^{N} \int_{E_{ij}} j(\sigma_h \cdot \nu_{ij})(w - \pi_h w) \, ds}{\| \nabla w \|_{2, \Omega}} \right\}.
\]
First term in sup

\[ \int_{T_i} (\text{div} \sigma_h + f)(w - \pi_h w) \, dx \leq \| \text{div} \sigma_h + f \|_{2,T_i} \| w - \pi_h w \|_{2,T_i} \]

\[ \leq c_i^T \| \text{div} \sigma_h + f \|_{2,T_i} \text{diam} (T_i) \| w \|_{1,2,\omega_N(T_i)}, \]

Then, the first sum is estimated as follows:

\[ \sum_{i=1}^{N} \int_{T_i} (\text{div} \sigma_h + f)(w - \pi_h w) \, dx \leq \]

\[ \leq d_1 \left( \sum_{i=1}^{N} \left( c_i^T \right)^2 \text{diam} (T_i)^2 \| \text{div} \sigma_h + f \|_{2,T_i}^2 \right)^{1/2} \| w \|_{1,2,\Omega}, \]

where the constant \( d_1 \) depends on the maximal number of elements in the set \( \omega_N(T_i) \).
Second term in sup

For the second one, we have

\[
\sum_{i=1}^{N} \sum_{j>i}^{N} \int_{E_{ij}} j(\sigma_h \cdot \nu_{ij})(w - \pi_h w) \, dx \leq \nabla (\sigma_h \cdot \nu_{ij}) \| w \|_{1,2,\omega_E(T_i)} \leq d_2 \left( \sum_{i=1}^{N} \sum_{j>i}^{N} (c_{ij}^E)^2 \| E_{ij} \|_{2, E_{ij}} \right)^{1/2} \| w \|_{1,2,\Omega},
\]

where \( d_2 \) depends on the maximal number of elements in the set \( \omega_E(T_i) \).
Residual type error estimate

By the above estimates we obtain

\[ \| R(u_h) \| \leq C_0 \left( \left( \sum_{i=1}^{N} (c_i^T)^2 \text{diam}(T_i)^2 \| \text{div} \sigma_h + f \|_{2,T_i}^2 \right)^{1/2} + \left( \sum_{i=1}^{N} \sum_{j>i}^{N} (c_{ij}^E)^2 |E_{ij}| \| j(\sigma_h \cdot \nu_{ij}) \|_{2,E_{ij}}^2 \right)^{1/2} \right). \quad (54) \]

Here \( C_0 = C_0(d_1, d_2) \). We observe that the right-hand side is the sum of local quantities (usually denoted by \( \eta(T_i) \)) multiplied by constants depending on properties of the chosen splitting \( F_h \).
Error indicator for quasi-uniform meshes

For quasi–uniform meshes all generic constants $c_i^T$ have approximately the same value and can be replaced by a single constant $c_1$. If the constants $c_{ij}^E$ are also estimated by a single constant $c_2$, then we have

$$\| R(u_h) \| \leq C \left( \sum_{i=1}^{N} \eta^2(T_i) \right)^{1/2},$$

where $C = C(c_1, c_2, C_0)$ and

$$\eta^2(T_i) = c_1^2 \text{diam}(T_i)^2 \| \text{div} \sigma_h + f \|_{2, T_i}^2 + \frac{c_2^2}{2} \sum_{E_{ij} \subset \partial T_i} |E_{ij}| \| j(\sigma_h \cdot \nu_{ij}) \|_{2, E_{ij}}^2.$$

The multiplier $1/2$ arises, because any interior edge is common for two elements.
General form of the residual type a posteriori error estimates is as follows:

\[ \| u - u_h \| \leq M(u_k, c_1, c_2, ...c_N, D), \]

where \( D \) is the data set, \( u_h \) is the Galerkin approximation, and \( c_i, i = 1, 2, ...N \) are the interpolation constants. The constants depend on the mesh and properties of the special type interpolation operator. The number \( N \) depends on the dimension of \( V_h \) and may be rather large. If the constants are not sharply defined, then this functional is not more than a certain error indicator. However, in many cases it successfully works and was used in numerous researches.
Comment 2

It is worth noting that for nonlinear problems the dependence between the error and the respective residual is much more complicated. A simple example below shows that the value of the residual may fail to control the distance to the exact solution.
It is commonly accepted that this approach brings its origin from the papers
Also, we recommend the books
A posteriori error indicators based on post-processing of computed solutions

A posteriori methods based on post-processing

Post-processing of approximate solutions is a numerical procedure intended to modify already computed solution in such a way that the post-processed function would fit some a priori known properties much better than the original one.
Let $e$ denote the error of an approximate solution $v \in V$ and $\mathcal{E}(v) : V \to \mathbb{R}_+$ denotes the value of an error estimator computed on $v$.

**Definition**

The estimator is said to be **equivalent to the error** for the approximations $v$ from a certain subset $\tilde{V}$ if

$$c_1 \mathcal{E}(v) \leq \|e\| \leq c_2 \mathcal{E}(v) \quad \forall v \in \tilde{V}$$
Definition

The ratio

\[ i_{\text{eff}} := 1 + \frac{\mathcal{E}(v) - \|e\|}{\|e\|} \]

is called the **effectivity index** of the estimator \( \mathcal{E} \).

Ideal estimator has \( i_{\text{eff}} = 1 \). However, in real life situations it is hardly possible, so that values \( i_{\text{eff}} \) in the diapason from 1 to 2-3 are considered as quite good.
In FEM methods with mesh size $h$ one other term is often used:

**Definition**

The estimator $\mathcal{E}$ is called **asymptotically equivalent to the error** if for a sequence of approximate solutions $\{u_h\}$ obtained on consequently refined meshes there holds the relation

$$\inf_{h \to 0} \frac{\mathcal{E}(u_h)}{\|u - u_h\|} = 1$$

It is clear that an estimator may be asymptotically exact for one sequence of approximate solutions (e.g. computed on regular meshes) and not exact for another one.
Typically, the function $T_u h$ (where $T$ is a certain linear operator, e.g., $\nabla$) lies in a space $U$ that is wider than the space $\overline{U}$ that contains $T u$. If we have a computationally inexpensive continuous mapping $G$ such that $G(T v_h) \in U$, $\forall v_h \in V_h$. then, probably, the function $G(T_u h)$ is much closer to $T u$ than $T_u h$. 
These arguments form the basis of various post-processing algorithms that change a computed solution in accordance with some a priori knowledge of properties of the exact solution. If the error caused by violations of a priori regularity properties is dominant and the post-processing operator $G$ is properly constructed, then

$$ \| G T u_h - T u \| \ll \| T u_h - T u \|. $$

In this case, the explicitly computable norm $\| G T u_h - T u_h \|$ can be used to evaluate upper and lower bounds of the error. Indeed, assume that there is a positive number $\alpha < 1$ such that for the mapping $T$ the estimate

$$ \| G T u_h - T u \| \leq \alpha \| T u_h - T u \|. $$
Two–sided estimate

Then, for $e = u_h - u$ we have

$$(1 - \alpha) \|Te \| = (1 - \alpha) \|Tu_h - Tu \| \leq$$

$$\leq \|Tu_h - Tu \| - \|GTu_h - Tu \| \leq$$

$$\leq \|GTu_h - Tu_h \| \leq$$

$$\leq \|GTu_h - Tu \| + \|Tu_h - Tu \| \leq$$

$$\leq (1 + \alpha) \|Tu_h - Tu \| = (1 + \alpha) \|Te \|.$$

Thus, if $\alpha << 1$, then

$$\|Tu_h - Tu \| \simeq \|GTu_h - Tu_h \|.$$ 

and the right-hand can be used as an error indicator.
Post-processing by averaging

Post-processing operators are often constructed by averaging $T u_h$ on finite element patches or on the entire domain.

**Integral averaging on patches**

If $T u_h \in L^2$, then post-processing operators are obtained by various averaging procedures. Let $\Omega_i$ be a patch of $M_i$ elements, i.e.,

$$\overline{\Omega_i} = \bigcup T_{ij}, \quad j = 1, 2, \ldots M_i.$$ 

Let $P^k(\Omega_i, \mathbb{R}^n)$ be a subspace of $\overline{U}$ that consists of vector-valued polynomial functions of degrees less than or equal to $k$. Define $g_i \in P^k(\Omega_i, \mathbb{R}^n)$ as the minimizer of the problem:

$$\inf_{g \in P^k(\Omega_i, \mathbb{R}^n)} \int_{\Omega_i} |g - T u_h|^2 \, dx.$$
The minimizer $g_i$ is used to define the values of an averaged function at some points (nodes). Further, these values are utilized by a prolongation procedure that defines an averaged function

$$G T u_h : \Omega \rightarrow \mathbb{R}.$$ 

Consider the simplest case. Let $T$ be the operator $\nabla$ and $u_h$ be a piecewise affine continuous function. Then,

$$\nabla u_h \in P^0(T_{ij}, \mathbb{R}^n) \text{ on each } T_{ij} \subset \Omega_i.$$ 

We denote the values of $\nabla u_h$ on $T_{ij}$ by $(\nabla u_h)_{ij}$. 
Set $k = 0$ and find $g_i \in P^0$ such that

$$\int_{\Omega_i} |g_i - \nabla u_h|^2 \, dx = \inf_{g \in P^0(\Omega_i)} \int_{\Omega_i} |g - \nabla u_h|^2 \, dx =$$

$$= \inf_{g \in P^0(\Omega_i)} \left\{ |g|^2 |\Omega_i| - 2g \cdot \sum_{j=1}^{M_i} (\nabla u_h)_{ij} |T_{ij}| + \sum_{j=1}^{M_i} |(\nabla u_h)_{ij}|^2 |T_{ij}| \right\}.$$  

It is easy to see that $g_i$ is given by a weighted sum of $(\nabla u_h)_{ij}$, namely,

$$g_i = \sum_{j=1}^{M_i} \frac{|T_{ij}|}{|\Omega_i|} (\nabla u_h)_{ij}.$$ 

Set

$$G(\nabla u_h)(x_i) = g_i.$$
Repeat this procedure for all nodes and define the vector-valued function $G \nabla (u_h)$ by the piecewise affine prolongation of these values. For regular meshes with equal $|T_{ij}|$, we have

$$g_i = \sum_{j=1}^{M_i} \frac{1}{M_i} (\nabla u_h)_{ij}.$$

Various averaging formulas of this type are represented in the form

$$g_i = \sum_{j=1}^{M_i} \lambda_{ij} (\nabla u_h)_{ij}, \quad \sum_{j=1}^{M_i} \lambda_{ij} = 1,$$

where $\lambda_{ij}$ are the weight factors. For internal nodes, they may be taken, e.g., as follows

$$\lambda_{ij} = \frac{|\gamma_{ij}|}{2\pi}, \quad |\gamma_{ij}| \text{ is the angle.}$$
However, if a node belongs to the boundary, then it is better to choose special weights. Their values depend on the mesh and on the type of the boundary. Concerning this point see

Consider the problem

\[
\inf_{g \in \mathbb{P}^k(\Omega_i)} \sum_{s=1}^{m_i} |g(x_s) - T u_h(x_s)|^2,
\]

where the points \(x_s\) are specially selected in \(\Omega_i\). Usually, the points \(x_s\) are the so-called \textbf{superconvergent points}.

Let \(g_i \in \mathbb{P}^k(\Omega_i)\) be the minimizer of this problem.

If \(k = 0\), and \(T = \nabla\) then

\[
g_i = \frac{1}{m_i} \sum_{s=1}^{m_i} \nabla u_h(x_s).
\]
Global averaging

Global averaging makes the post-processing not on patches, but on the whole domain.

Assume that $T\mathbf{u}_h \in L^2$ and find $\bar{g}_h \in V_h(\Omega) \subset \overline{U}$ such that

$$\|\bar{g}_h - T\mathbf{u}_h\|^2_{\Omega} = \inf_{g_h \in V_h(\Omega)} \|g_h - T\mathbf{u}_h\|^2_{\Omega}.$$  

The function $\bar{g}_h$ can be viewed as $G T\mathbf{u}_h$. Very often $\bar{g}_h$ is a better image of $T\mathbf{u}$ than the functions obtained by local procedures.
Moreover, mathematical justifications of the methods based on global averaging procedures can be performed under weaker assumptions what makes them applicable to a wider class of problems see, e.g.,

Solve the boundary–value problem

$$\Delta u + f = 0, \quad u = 0 \text{ on } \partial \Omega$$

by $h$-version FEM (use Matlab or another code). Apply the simplest gradient–averaging error indicator to indicate the error distribution. Compare it with the distribution of true error (the latter can be extracted from a solution on a much finer mesh).
Justifications of the method. Superconvergence

Let $u_h$ be a Galerkin approximation of $u$ computed on $V_h$. For piecewise affine approximations of the diffusion problem we have the estimate

$$\|\nabla (u - u_h)\|_{2,\Omega} \leq c_1 h,$$

$$\|u - u_h\|_{2,\Omega} \leq c_2 h^2.$$

However, it was discovered see, e.g.,
L. B. Wahlbin. Lecture Notes. Springer, 1969 that in certain cases this rate may be higher. For example it may happen that

$$|u(x_s) - u_h(x_s)| \leq Ch^{2+\sigma} \quad \sigma > 0$$

at a superconvergent point $x_s$. 
Certainly, existence and location of superconvergent points strongly depends on the structure of $T_h$.

For the paradigm of the diffusion problem we say that an operator $G$ possesses a superconvergence property in $\omega \subset \Omega$ if

$$\| \nabla u - G \nabla u_h \|_{2,\omega} \leq c_2 h^{1+\sigma},$$

where the constant $c_2$ may depend on higher norms of $u$ and the structure of $T_h$. 

By exploiting the superconvergence properties, e.g.,

$$\|\nabla u - \mathcal{G}\nabla u_h\|_{2,\omega} \leq c_2 h^{1+\sigma},$$

while

$$\|\nabla u - \nabla u_h\|_{2,\omega} \leq c_2 h,$$

one can usually construct a simple post-processing operator $\mathcal{G}$ satisfying the condition

$$\|\mathcal{G}\nabla u_h - \nabla u\| \leq \alpha \|\nabla u_h - \nabla u\|.$$

where the value of $\alpha$ decreases as $h$ tends to zero.
Since

\[ \| \mathcal{G} \nabla u_h - \nabla u_h \| \leq \| \nabla u_h - \nabla u \| + \| \mathcal{G} \nabla u_h - \nabla u \|, \]

\[ \| \mathcal{G} \nabla u_h - \nabla u_h \| \geq \| \nabla u_h - \nabla u \| - \| \mathcal{G} \nabla u_h - \nabla u \|. \]

where the first term in the right–hand side is of the order $h$ and the second one is of $h^{1+\delta}$. We see that

\[ \| \mathcal{G} \nabla u_h - \nabla u_h \| \sim h \]

Therefore, we observe that in the decomposition

\[ \| \nabla (u_h - u) \| \leq \| \nabla u_h - \mathcal{G} \nabla u_h \| + \| \mathcal{G} \nabla u_h - \nabla u \| \]

asymptotically dominates the second directly computable term.
Thus, we obtain a simple error indicator:

\[ \| \nabla (u_h - u) \| \approx \| \nabla u_h - \mathcal{G} \nabla u_h \|. \]

Note that

\[ i_{\text{eff}} = \frac{\| \nabla (u_h - u) \|}{\| \nabla u_h - \mathcal{G} \nabla u_h \|} \approx 1 + ch^\delta \]

so that this error indicator is \textbf{asymptotically exact} provided that \( u_h \) is a Galerkin approximation, \( u \) is sufficiently regular and \( h \) is small enough. Such type error indicators (often called \textit{ZZ indicators} by the names of Zienkiewicz and Zhu) are widely used as cheap error indicators in engineering computations.
Some references

Post-processing by equilibration

For a solution of the diffusion problem we know that

\[ \text{div}\sigma + f = 0, \]

where \( \sigma = A\nabla u \). This suggests an idea to construct an operator \( G \) such that

\[ \text{div}(G(A\nabla u_h)) + f = 0. \]

If \( G \) possesses additional properties (linearity, boundedness), then we may hope that the function \( G A\nabla u_h \) is closer to \( \sigma \) than \( A\nabla u_h \) and use the quantity \( \|A\nabla u_h - G A \nabla u_h\| \) as an error indicator.
This idea can be applied to an important class of problems

\[ \Lambda^*Tu + f = 0, \quad Tu = \mathcal{A}\Lambda u, \]  

(56)

where \( \mathcal{A} \) is a positive definite operator, \( \Lambda \) is a linear continuous operator, and \( \Lambda^* \) is the adjoint operator.

In continuum mechanics, equations of the type (56) are referred to as the equilibrium equations. Therefore, it is natural to call an operator \( G \) an equilibration operator.

If the equilibration has been performed exactly then it is not difficult to get an upper error bound. However, in general, this task is either cannot be fulfilled or lead to complicated and expensive procedures. Known methods are usually end with approximately equilibrated fluxes.
Global error estimates give a general idea on the quality of an approximate solution and stopping criteria. However, often it is useful to estimate the errors in terms of specially selected linear functionals $\ell_s$, $s = 1, 2, \ldots, M$, e.g.,

$$< \ell, v - u > = \int_\Omega \varphi_0 (v - u) \, dx,$$

where $\phi$ is a locally supported function. Since

$$| < \ell, u - u_h > | \leq \|\ell\| \|u - u_h\|_V,$$

we can obtain such an estimate throughout the global a posteriori estimate. However, in many cases, such a method will strongly overestimate the quantity.
A posteriori error estimates constructed with help of adjoint problems

Adjoint problem

A posteriori estimates of the errors evaluated in terms of linear functionals are derived by attracting the adjoint boundary-value problem whose right-hand side is formed by the functional $\ell$.

Let us represent this idea in the simplest form. Consider a system

$$ Au = f, $$

where $A$ is a positive definite matrix and $f$ is a given vector. Let $v$ be an approximate solution. Define $u_\ell$ by the relation

$$ A^* u_\ell = \ell, $$

where $A^*$ is the matrix adjoint to $A$. Then,

$$ \ell \cdot (u - v) = A^* u_\ell \cdot u - \ell \cdot v = f \cdot u_\ell - \ell \cdot v = (f - Av) \cdot u_\ell $$
Certainly, the above consideration holds in a more general (operator) sense, so that for a pair of operators $A$ and $A^*$ we have

$$\langle \ell, u - v \rangle = \langle f - Av, u_\ell \rangle .$$

and find the error with respect to a linear functional by the product of the residual and the exact solution of the adjoint problem:

$$A^* u_\ell = \ell .$$

Practical application of this principle depends on the ability to find either $u_\ell$ or its sharp approximation.
Consider again the diffusion problem. Now, it is convenient to denote the solution of the original problem by $u_f$, i.e

$$\int_{\Omega} A \nabla u_f \cdot \nabla w \, dx = \int_{\Omega} f w \, dx, \quad \forall w \in V_0(\Omega).$$

Since in our case $A = A^*$, the adjoint problem is to find $u_\ell \in V_0(\Omega)$ such that

$$\int_{\Omega} A \nabla u_\ell \cdot \nabla w \, dx = \int_{\Omega} \ell w \, dx, \quad \forall w \in V_0(\Omega).$$
Let $\Omega$ be divided into a number of elements $T_i, i = 1, 2, ..., N$. Given approximations on the elements, we define a finite-dimensional subspace $V_{0h} \subset V_0(\Omega)$ and the Galerkin approximations $u_{fh}$ and $u_{\ell h}$:

$$\int_{\Omega} A \nabla u_{fh} \cdot \nabla w_h \, dx = \int_{\Omega} f w_h \, dx, \quad \forall w_h \in V_{0h},$$

$$\int_{\Omega} A \nabla u_{\ell h} \cdot \nabla w_h \, dx = \int_{\Omega} \ell w_h \, dx, \quad \forall w_h \in V_{0h}.$$

Since

$$\int_{\Omega} \ell (u_f - u_{fh}) \, dx = \int_{\Omega} A \nabla u_{\ell} \cdot \nabla (u_f - u_{fh}) \, dx$$

and

$$\int_{\Omega} A \nabla u_{\ell h} \cdot \nabla (u_f - u_{fh}) \, dx = 0,$$
We arrive at the relation

$$
\int_{\Omega} \ell (u_f - u_{fh}) \, dx = \int_{\Omega} A \nabla (u_\ell - u_{\ell h}) \cdot \nabla (u_f - u_{fh}) \, dx
$$

(58)

whose right-hand side is expressed in the form

$$
\sum_{i=1}^{N} \int_{T_i} A \nabla (u_f - u_{fh}) \cdot \nabla (u_\ell - u_{\ell h}) \, dx = \\
\sum_{i=1}^{N} \left\{ - \int_{T_i} \text{div} \left( A \nabla (u_f - u_{fh}) \right) (u_\ell - u_{\ell h}) \, dx + \\
\frac{1}{2} \int_{\partial T_i} \mathbf{j} (\nu_i \cdot A \nabla (u_f - u_{fh})) (u_\ell - u_{\ell h}) \, ds \right\}.
$$

This relation implies the estimate
A posteriori error estimates constructed with help of adjoint problems

\[
\int_\Omega \ell(u_f - u_{fh}) \, dx = \sum_{i=1}^{N} \left\{ \| \text{div} A \nabla (u_f - u_{fh}) \|_{2,T_i} \, \| u_{\ell} - u_{\ell h} \|_{2,T_i} + \\
+ \frac{1}{2} \| j(\nu_i \cdot A \nabla (u_f - u_{fh})) \|_{2,\partial T_i} \, \| u_{\ell} - u_{\ell h} \|_{2,\partial T_i} \right\} = \\
= \sum_{i=1}^{N} \left\{ \| f + \text{div} A \nabla u_{fh} \|_{2,T_i} \, \| u_{\ell} - u_{\ell h} \|_{2,T_i} + \\
+ \frac{1}{2} \| j(\nu_i \cdot A \nabla u_{fh}) \|_{2,\partial T_i} \, \| u_{\ell} - u_{\ell h} \|_{2,\partial T_i} \right\}.
\]

Here, the principal terms are the same as in the explicit residual method, but the weights are given by the norms of \( u_{\ell} - u_{\ell h} \).
A posteriori error estimates constructed with help of adjoint problems

Assume that $u_\ell \in H^2$ and $u_{\ell h}$ is constructed by piecewise affine continuous approximations. Then the norms $\|u_\ell - u_{\ell h}\|_{T_i}$ and $\|u_\ell - u_{\ell h}\|_{2,\partial T_i}$ are estimated by the quantities $h^\alpha |u_\ell|_{2,2,T_i}$ with $\alpha = 1$ and $1/2$ and the multipliers $\hat{c}_i$ and $\hat{c}_{ij}$, respectively.

In this case, we obtain an estimate with constants defined by the standard $\quad H^2 \to V_{0h}$

interpolation operator whose evaluation is much simpler than that of the constants arising in the $\quad H^1 \to V_{0h}$

interpolation.
A posteriori error estimates constructed with help of adjoint problems

A posteriori estimates in $L^2$–norm

In principle, this technology can be exploited to evaluate estimates in $L^2$–norm. Indeed,

$$
\|u_f - u_{fh}\| = \sup_{\ell \in L^2} \frac{(\ell, u_f - u_{fh})}{\|\ell\|} = \sup_{\ell \in L^2} \frac{(A\nabla u_\ell, \nabla (u_f - u_{fh}))}{\|\ell\|} =
$$

$$
= \sup_{\ell \in L^2} \frac{(A\nabla (u_\ell - \pi_h (u_\ell)), \nabla (u_f - u_{fh}))}{\|\ell\|} =
$$

$$
= \sup_{\ell \in L^2} \frac{(\nabla (u_\ell - \pi_h (u_\ell)), A\nabla (u_f - u_{fh}))}{\|\ell\|} =
$$

$$
\sum_{i=1}^{N} \left\{ \frac{\int_{T_i} \nabla (u_\ell - \pi_h (u_\ell)), A\nabla (u_f - u_{fh}) \, dx}{\|\ell\|} \right\}
$$

Mat-5.210 Special Course in Computational Mechanics, Autumn 2006, Helsinki University of Technology

S. Repin

A POSTERIORI ANALYSIS FOR PDE'S.
Integrating by parts, we obtain

\[
\sum_{i=1}^{N} \left\{ \| f + \text{div} A \nabla u_{fh} \|_{T_i} \| u_{\ell} - \pi_h(u_{\ell}) \|_{T_i} + \frac{1}{2} \| j(\nu_i \cdot A \nabla u_{fh}) \|_{\partial T_i} \| u_{\ell} - \pi_h(u_{\ell}) \|_{\partial T_i} \right\}
\]

\[
\| \ell \|
\]

If for any \( \ell \in L^2 \) the adjoint problem has a regular solution (e.g., \( u_{\ell} \in H^2 \)), so that we could combine the standard interpolation estimate for the interpolant of \( u_{\ell} \) with the regularity estimate for the PDE (e.g., \( \| u_{\ell} \| \leq C_1 \| \ell \| \)), then we obtain

\[
\| u_{\ell} - \pi_h(u_{\ell}) \|_{T_i} \leq C_1 h^{\alpha_1} \| \ell \|, \quad \| u_{\ell} - \pi_h(u_{\ell}) \|_{\partial T_i} \leq C_1 h^{\alpha_2} \| \ell \|
\]

with certain \( \alpha_k \).

Under the above conditions \( \| \ell \| \) is reduced and we arrive at the estimate, in which the element residuals and interelement jumps are weighted with factors \( C_1 h^{\alpha_1} \) and \( C_2 h^{\alpha_2} \).
A posteriori error estimates constructed with help of adjoint problems

References

Methods using adjoint problems has been investigated in the works of R. Becker, C. Johnson, R. Rannacher and other scientists. A more detailed exposition of these works can be found in

Concerning error estimation in goal–oriented quantities we refer, e.g., to

A posteriori error estimates constructed with help of adjoint problems

Comment

In the literature devoted to a posteriori error analysis one can find terms like "duality approach to a posteriori error estimation" or "dual-based error estimates". However, the essence behind such a terminology may be quite different because the word "duality" is used in 3 different meanings:

(a) **Duality in the sense of functional spaces.** We have seen that if for the equation $Lu = f$ errors are measured in the original (energy) norm then a consistent upper bound is given by the residual in the norm of the space topologically dual to a subspace of the energy space (e.g., $H^{-1}$).

(b) **Duality in the sense of using the Adjoint Problem.**

(c) **Duality in the sense of the Theory of the Calculus of Variations.**
In the next lecture we will proceed to the detailed exposition of the approach (c).
In the lecture, we derive Functional A Posteriori Estimate for the problem

\[ \Delta u + f = 0, \quad \Omega \]

\[ u = 0 \quad \partial \Omega. \]

and discuss its meaning, principal features and practical implementation.

2. How to derive them? Paradigm of a simple elliptic problem
3. How to use them in practice?
   4. Examples.
Functional A Posteriori Estimate is a computable majorant of the difference between exact solution \( u \) and any conforming approximation \( v \) having the general form:

\[
\Phi(u - v) \leq M(D, v) \quad \forall v \in V
\]  

(59)

\( D \) is the data set (coefficients, domain, parameters, etc.), \( \Phi : V \rightarrow \mathbb{R}^+ \) is a given functional. 

\( M \) must be computable and continuous in the sense that

\[
M(D, v) \rightarrow 0, \quad \text{if} \ v \rightarrow u
\]
Types of $\Phi$

- Energy norm
  \[ \Phi(u - v) = \|u - v\|_\Omega \]
- Local norm
  \[ \Phi(u - v) = \|u - v\|_\omega \]
- Goal–oriented quantity
  \[ \Phi(u - v) = (\ell, u - v) \]

Functional a posteriori estimate gives complete solution of the error control problem from the viewpoint of the MATHEMATICAL THEORY of PDE's.
These estimates are derived by purely functional methods using the analysis of variational problems or integral identities.
**Variational method 96’-97’**

Exploits variational structure of the original problem and Duality Theory in the Calculus of Variations.

See

A systematic exposition of the variational approach to deriving Functional a Posteriori Estimates can be found in

Nonvariational method 2000’

Derives a posteriori estimates by certain transformations of integral identities.

Basic idea of the method is presented in

Other publications:

Let us consider both methods in application to our basic problem.
Variational Method

Let \( u \) be a (generalized) solution of the problem

\[
\Delta u + f = 0, \quad \Omega \quad u = 0 \ | \partial \Omega.
\]

As we have seen in Lecture 1, this problem is equivalent to the following variational problem:

**Problem \( \mathcal{P} \).** Find \( u \in V_0 := H^1_0(\Omega) \) such that

\[
J(u) = \inf_{v \in V_0} J(v),
\]

where

\[
J(v) = \frac{1}{2} \| \nabla v \|^2 - (f, v).
\]

By the reasons that we discussed earlier this problem has a unique solution.
Lagrangian

Note that

\[ J(v) = \sup_{y \in Y} L(\nabla v, y), \quad L(\nabla v, y) = \int_{\Omega} \left( \nabla v \cdot y - \frac{1}{2} |y|^2 - fv \right) dx \]

where \( Y = L^2(\Omega, \mathbb{R}^n) \). Indeed, the value of the above supremum cannot exceed the one we obtain if for almost all \( x \in \Omega \) solve the pointwise problems

\[ \sup_{y(x)} (\nabla v)(x) \cdot y(x) - \frac{1}{2} |y(x)|^2 \quad x \in \Omega \]

whose upper bound is attained if set \( y(x) = (\nabla v)(x) \). Since \( \nabla v \in Y \), we observe that the respective maximizer belongs to \( Y \) and, therefore

\[ \sup_{y \in Y} L(\nabla v, y) = L(\nabla v, \nabla v) = J(v). \]
Minimax Formulations

Then, the original problem comes in the minimax form:

\[(P) \quad \inf_{v \in V_0} \sup_{y \in Y} L(\nabla v, y)\]

If the order of inf and sup is changed, then we arrive at the so-called dual problem

\[(P^*) \quad \sup_{y \in Y} \inf_{v \in V_0} L(\nabla v, y)\]

Note that

\[
\inf_{v \in V_0} \int_{\Omega} \left( \nabla v \cdot y - \frac{1}{2} |y|^2 - fv \right) dx = -\frac{1}{2} \|y\|^2 + \inf_{v \in V_0} \int_{\Omega} (\nabla v \cdot y - fv) dx =
\]

\[
= \begin{cases} 
-\frac{1}{2} \|y\|^2 & \text{if } y \in Q_f := \{y \in Y \mid \text{div}y + f = 0\} \\
-\infty & \text{if } y \not\in Q_f 
\end{cases}
\]
Thus, we observe that the dual problem has the form: find $p \in Q_f$ such that
\[-I^*(p) = \sup_{y \in Q_f} -I^*(y)\]
where
\[I^*(q) = \frac{1}{2} \|q\|^2\]

How are these two problems related?

First, we establish one relation that holds regardless of the structure of the Lagrangian.
Lemma

Let \( L(x, y) \) be a functional defined on the elements of two nonempty sets \( X \) and \( Y \). Then

\[
\sup_{y \in Y} \inf_{x \in X} L(x, y) \leq \inf_{x \in X} \sup_{y \in Y} L(x, y). \tag{60}
\]

Proof

It is easy to see that

\[
L(x, y) \geq \inf_{\xi \in X} L(\xi, y), \quad \forall x \in X, \ y \in Y.
\]

Taking the supremum over \( y \in Y \), we obtain
proof

\[ \sup_{y \in Y} L(x, y) \geq \sup_{y \in Y} \inf_{\xi \in X} L(\xi, y), \quad \forall x \in X. \]

The left-hand side depends on \(x\), while the right-hand side is a number. Thus, we may take infimum over \(x \in X\) and obtain the inequality

\[ \inf_{x \in X} \sup_{y \in Y} L(x, y) \geq \sup_{y \in Y} \inf_{\xi \in X} L(\xi, y). \]

Therefore, we always have

\[ \sup P^* \leq \inf P. \]
Duality relations

However, in our case we have a stronger relation, namely

$$\sup \mathcal{P}^* = \inf \mathcal{P}$$

To prove this fact, we note that

$$\int_{\Omega} \nabla u \cdot \nabla v \, dx = \int_{\Omega} fv \, dx \quad \forall v \in V_0.$$

Therefore $p = \nabla u \in Q_f$ and

$$-I^*(p) = -\frac{1}{2} \|\nabla u\|^2 = \int_{\Omega} \left( \frac{1}{2} |\nabla u|^2 - |\nabla u|^2 \right) dx = \int_{\Omega} \left( \frac{1}{2} |\nabla u|^2 - fu \right) dx = J(u).$$
Let us use the Mikhlin’s estimate established in Lecture 2:

\[
\frac{1}{2} \| \nabla (u - v) \|^2 \leq J(v) - J(u).
\]

Since \( J(u) = -I^*(p) \), we have

\[
\frac{1}{2} \| \nabla (u - v) \|^2 \leq J(v) + I^*(p) \leq J(v) + I^*(q) \quad \forall q \in Q_f.
\]

Reform this estimate by using the fact that \( q \in Q_f \).

\[
J(v) + I^*(q) = \frac{1}{2} \| \nabla v \|^2 - (f, v) + \frac{1}{2} \| q \|^2
\]

\[
= \frac{1}{2} \| \nabla v \|^2 + \frac{1}{2} \| q \|^2 - (\nabla v, q) = \frac{1}{2} \| \nabla v - q \|^2.
\]
Now, we have

$$\|\nabla (v - u)\| \leq \|\nabla v - q\| \quad \forall q \in Q_f.$$

Take arbitrary \( y \in L^2(\Omega) \). Then,

$$\|\nabla (v - u)\| \leq \|\nabla v - y\| + \inf_{q \in Q_f} \|y - q\|.$$

**How to estimate the above infimum?**

Various methods give one and the same answer:

\[
\inf_{q \in Q_f} \|y - q\| \leq \|\text{div} y + f\| \quad y \in L^2(\Omega), \tag{61}
\]

\[
\inf_{q \in Q_f} \|y - q\| \leq C_\Omega \|\text{div} y + f\| \quad y \in H(\Omega, \text{div}), \tag{62}
\]
Proof

To prove these estimates we consider an auxiliary problem

\[ \Delta \eta + f + \text{div} y = 0 \quad \Omega \quad \eta = 0 \quad \partial \Omega. \]

\[ \int_{\Omega} \nabla \eta \cdot \nabla w \, dx = \int_{\Omega} (fw - y \cdot \nabla w) \, dx \]

Thus, \( \bar{q} \in Q_f \) !!!
Since $\eta$ is a solution of the boundary–value problem with right–hand side $\text{div } y + f \in H^{-1}$, we have

$$\|\nabla \eta\| \leq \left[\text{div } y + f\right],$$

Then

$$\inf_{q \in Q_f} \|y - q\| \leq \|y - \bar{q}\| = \|\nabla \eta\| \leq \left[\text{div } y + f\right].$$

Here

$$\left[\text{div } y + f\right] = \sup_{w \in V_0} \int_{\Omega} (y \cdot \nabla w - fw)dx$$
If \( y \) has a square summable divergence, then we have

\[
\| \text{div} y + f \| = \sup_{w \in V_0} \frac{\int_{\Omega} (\text{div} y + f) w \, dx}{\| \nabla w \|} \leq C_\Omega \| \text{div} y + f \|,
\]

where \( C_\Omega \) is the constant in the Friederichs–Steklov inequality for the domain \( \Omega \). We observe that

a "noncomputable" negative norm has been estimated by a "computable" one without an attraction of Galerkin orthogonality and local (mesh–dependent) constants.
Thus, for any $y \in H(\Omega, \text{div})$ we obtain

$$\| \nabla (v - u) \| \leq \| \nabla v - y \| + \inf_{q \in Q_f} \| y - q \| \leq \| \nabla v - y \| + C_\Omega \| \text{div} y + f \|.$$ 

Above presented *modus operandi* can be viewed as a simplest version of the variational approach to the derivation of Functional Error Majorants.
Deriving a posteriori estimates from integral identities.

For many problems the variational techniques cannot be applied (e.g., because they may have no variational formulation).

In S. Repin. Two-sided estimates for deviation from an exact solution to uniformly elliptic equation. *Trudi St.-Petersburg Math. Society*, 9(2001), translated in *American Mathematical Translations Series 2, 9*(2003)) it was suggested another method, which is based on certain transformations of integral identities.
Non–variational method in the simplest case

Let us expose its simplest version adapted to our model problem. We have

\[ \int_{\Omega} \nabla(u - v) \nabla w \, dx = \int_{\Omega} (fw - \nabla v \cdot \nabla w) \, dx \]

In order to get an upper bound of \( \|\nabla(u - v)\| \) we use the relation

\[ \int_{\Omega} (\text{div}yw + \nabla w \cdot y) \, dx = 0 \quad \forall w \in V_0 \]

valid for any \( y \in H(\Omega, \text{div}) \).
We have

\[
\int_{\Omega} (\nabla v \cdot \nabla w - fw) \, dx = \\
\int_{\Omega} (\nabla v \cdot \nabla w - fw - (\text{div} \, w + \nabla \cdot y)) \, dx = \\
\int_{\Omega} ((\nabla v - y) \cdot \nabla w - (f + \text{div} \, y)w) \, dx \leq \\
\|\nabla v - y\| \|\nabla w\| + \|f + \text{div} \, y\| \|w\| \leq \\
(\|\nabla v - y\| + C_\Omega \|f + \text{div} \, y\|) \|\nabla w\|.
\]
Set \( \mathbf{w} = \mathbf{u} - \mathbf{v} \).

\[
\int_{\Omega} |\nabla (\mathbf{u} - \mathbf{v})|^2 \, dx \leq (\|\nabla \mathbf{v} - \mathbf{y}\| + C_{\Omega}\|\mathbf{f} + \text{div} \mathbf{y}\|)\|\nabla (\mathbf{u} - \mathbf{v})\|.
\]

Thus, we find that

\[
\|\nabla (\mathbf{u} - \mathbf{v})\| \leq \|\nabla \mathbf{v} - \mathbf{y}\| + C_{\Omega}\|\mathbf{f} + \text{div} \mathbf{y}\|.
\]
For the problem

\[ \Delta u + f = 0, \quad u = 0 \text{ on } \partial \Omega \]

we have obtained the estimate

\[ \| \nabla(u - v) \| \leq \| \nabla v - y \| + C_\Omega \| \text{div}y + f \| \]  \hspace{1cm} (63)

The estimate is valid for any \( v \in V_0 \) and \( y \in H(\Omega, \text{div}) \).

Two terms in the right-hand side have a clear sense: they present measures of the errors in two basic relations

\[ p = \nabla u, \quad \text{div}p + f = 0 \quad \text{in } \Omega \]

that jointly form the equation.
The estimate is sharp

If set \( v = 0 \) and \( y = 0 \), we obtain the energy estimate for the generalized solution

\[
\| \nabla u \| \leq C_\Omega \| f \|.
\]

Therefore, no constant less than \( C_\Omega \) can be stated in the second term. If set \( y = \nabla u \), than the inequality holds as the equality. Thus, we see that the estimate (63) is sharp in the sense that the multipliers of both terms cannot be taken smaller and in the set of admissible \( y \) there exists a function that makes the inequality hold as equality.
The estimate as a quadratic functional

By means of the algebraic Young’s inequality

\[ 2ab \leq \beta a^2 + \frac{1}{\beta} b^2, \quad \beta > 0 \]

we rewrite this estimate in the form

\[
\| \nabla (u - v) \|^2 \leq (1 + \beta) \| \nabla v - y \|^2 + \frac{1 + \beta}{\beta} C^2_{\Omega} \| \text{div} y + f \|^2
\]

(64)

For any \( \beta \) the right-hand side is a quadratic functional. This property makes it possible to apply well known methods for the minimization with respect to \( y \).
Denote the right–hand side of (64) by $\mathcal{M}_\oplus$, i.e.,

$$\mathcal{M}_\oplus(v, y, \beta, C_\Omega, f) := (1 + \beta)\|\nabla v - y\|^2 + \frac{1 + \beta}{\beta} C_\Omega^2 \|\text{div}y + f\|^2.$$

This functional provides an upper bound for the norm of the deviation of $v$ from $u$. Therefore, it is natural to call it the **Deviation Majorant**.
BVP $\Delta u + f = 0$ has another variational formulation

\[
\inf_{v \in V_0, \beta > 0, y \in H(\Omega, \text{div})} \mathcal{M}_\oplus(v, y, \beta, C_\Omega, f)
\]

- Minimum of this functional is zero;
- it is attained if and only if $v = u$ and $y = A\nabla u$;
- $\mathcal{M}_\oplus$ contains only one global constant $C_\Omega$, which is problem independent;
In principle, one can select certain sequences of subspaces \( \{V_{hk}\} \in V_0 \) and \( \{Y_{hk}\} \in H(\Omega, \mathop{\text{div}}) \) and minimize the Error Majorant with respect to these subspaces

\[
\inf_{v \in V_{hk}, \beta > 0, y \in Y_{hk}} \mathcal{M}_\oplus(v, y, \beta, C_\Omega, f)
\]

If the subspaces are limit dense, then we would obtain a sequence of approximate solutions \((v_k, y_k)\) and the sequence of numbers

\[
\gamma_k := \inf_{\beta > 0} \mathcal{M}_\oplus(v_k, y_k, \beta, C_\Omega, f) \rightarrow 0
\]
How to use the Majorants in practice?

Consider **CONFORMING FEM APPROXIMATIONS**.

We have 3 basic ways to use the deviation estimate:

(a) **Direct** (via flux averaging on the mesh $\mathcal{T}_h$);
(b) **One step delay** (via flux averaging on the mesh $h_{\text{ref}}$);
(c) **Minimization** (minimization via $y$).
(a) Use recovered gradients

Let $u_h \in V_h$, then

$$ p_h := \nabla u_h \in L_2(\Omega, \mathbb{R}^d), \quad p_h \notin H(\Omega, \text{div}). $$

Use an averaging operator $G_h : L_2(\Omega, \mathbb{R}^d) \to H(\Omega, \text{div})$ and have a **directly computable estimate**

$$ \| \nabla (u - u_h) \| \leq \| \nabla u_h - G_h p_h \| + C_\Omega \| \text{div} G_h p_h + f \| $$
(b) Use recovered gradients from $\mathcal{T}_{h_{\text{ref}}}$

Let $u_1, u_2, \ldots, u_k, \ldots$ be a sequence of approximations on meshes $\mathcal{T}_{h_k}$. Compute $p_k := \nabla u_k$, average it by $G_k$ and for $u_{k-1}$ use the estimate

$$
\|u - u_{k-1}\| \leq \|\nabla u_{k-1} - G_k p_k\| + C_\Omega \|\text{div}G_k p_k + f\|$

This estimate gives a quantitative form of the Runge’s rule.
(c) Minimize $M_\oplus$ with respect to $y$.

Select a certain subspace $Y_\tau$ in $H(\Omega, \text{div})$. Generally, $Y_\tau$ may be constructed on another mesh $T_\tau$ and with help of different trial functions. Then

$$\|\nabla(u - u_h)\| \leq \inf_{y_h \in Y_h} \{ \|\nabla u_h - y_h\| + C_\Omega \|\text{div}y_h + f\| \}$$

The wider $Y_h \subset H(\Omega, \text{div})$ the sharper is the upper bound.
Quadratic type functional

From the technical point of view it is better to square both parts of the estimate and apply minimization to a quadratic functional, namely

$$\|\nabla (u - u_h)\|^2 \leq \inf_{y_h \in Y_h} \left\{ (1 + \beta) \|\nabla u_h - y_h\| + \right.$$ 

$$\left. + C_\Omega \left( 1 + \frac{1}{\beta} \right) \|\text{div}y_h + f\|^2 \right\}$$

Here, the positive parameter $\beta$ can be also used to minimize the right-hand side.
Before going to more complicated problems where Deviation Majorants are derived by a more sophisticated theory, we observe several simple examples that nevertheless reflect key points of the above method.
Simple 1-D problem

\[(\alpha(x) u')' = f(x),\]
\[u(a) = 0, \quad u(b) = u_b.\]

It is equivalent to the variational problem

\[J(v) = \int_a^b \left( \frac{1}{2} \alpha(x) |v'|^2 + f(x)v \right) \, dx.\]

Assume that the coefficient \(\alpha\) belongs to \(\mathbb{L}^\infty\) and bounded from below by a positive constant. Now

\[V_0 + u_0 = \{ v \in H^1(a, b) \mid v(a) = 0, v(b) = u_b \}.\]
Deviation Majorant

\[ \mathcal{M}_\oplus(v, \beta, y) = (1 + \beta) \left( \int_a^b |\alpha v' - y|^2 \, dx + \frac{C_{(a,b)}^2}{\beta} \int_a^b |y' - f|^2 \right) dx. \quad (65) \]

In this simple model, \( u \) can be presented in the form

\[ u(x) = \int_a^x \frac{1}{\alpha(t)} \int_a^t f(z) \, dz \, dt + \frac{x}{b} \left( u_b - \int_a^b \frac{1}{\alpha(t)} \int_a^t f(z) \, dz \, dt \right). \]

what gives an opportunity to verify how error estimation methods work.
Approximations

Let $V_h$ be made of piecewise–$P^1$ continuous functions on uniform splittings of the interval and consider approximations of the following types:

- Galerkin approximations;
- Approximations very close to Galerkin (sharp);
- Approximations which are ”good” but not Galerkin;
- Coarse (rough) approximations.

Our aim is to show that the Deviation Majorant can be effectively used as an error estimation instrument in all the above cases.
Computation of the Majorant

To find a sharp upper bound, we minimize $\mathcal{M}_\oplus$ with respect to $y$ and $\beta$ starting from the function $y_0 = G(v')$, where $G$ is a simple averaging operator, e.g., defined by the relations

$$G(v')(x_i) = \frac{1}{2} (v'(x_i - 0) + v'(x_i + 0)),$$

By the quantity

$$\inf_{\beta > 0} \mathcal{M}_\oplus(v, \beta, y_0),$$

we obtain a coarse upper bound of the error. It is further improved by minimizing $\mathcal{M}_\oplus$ with respect to $y$. 
Example

Let $\alpha(x) = 1$, $f(x) = c$, $a = 0$, $b = 1$, $u_b = 1$, e.g., we consider the problem

$$u'' = 2, \quad u(0) = 0, \quad u(1) = 1.$$  

In this case, $C_{(a,b)} = 1/\pi$ and

$$u = \frac{c}{2} x^2 + (1 - \frac{c}{2})x, \quad u' = cx + 1 - \frac{c}{2}.$$  

Take a rough approximation $v = x$. Then

$$\|u - v\|^2 = \int_0^1 c^2 (x - 0.5)^2 dx = \frac{c^2}{12} \approx 0.083c^2.$$
Exact solution and an approximation.
Various $y$ give different upper bounds

(a) Take $y = y' = 1$, then the first term in

$$
\mathcal{M}_\oplus(v, \beta, y) = (1 + \beta) \left( \int_0^1 |v' - y|^2 \, dx + \frac{1}{\pi^2 \beta} \int_0^1 |y' - f|^2 \, dx \right).
$$

vanishes and we have $\mathcal{M}_\oplus \rightarrow c^2 / \pi^2 \approx 0.101c^2$; as $\beta \rightarrow +\infty$. We see that this upper bound overestimates true error. Note that in this case, all sensible averagings of $v' = 1$ give exactly the same function: $G(1) = 1$! Therefore,

$$
G(v') - v' \equiv 0
$$

and formally ZZ indicator ”does not see the error”. 

---

Mat-5.210 Special Course in Computational Mechanics, Autumn 2006, S. Repin

Helsinki University of Technology

A POSTERIORI ANALYSIS FOR PDE's,
For the choice $y = v'$ the Majorant give a certain upper bound of the error (which is not so bad), but the integrand cannot indicate the distribution of local errors. Indeed, we have

$$M_\oplus = \frac{1}{\pi^2} \int_0^1 c^2 \, dx.$$ 

However, the integrand of the Majorant is a constant function, but the error is distributed in accordance with a parabolic law:

$$(u - v)' = c(x - 0.5)^2.$$
(b). Take $y = cx + 1 - c/2$. Then, $y' = c$ and the second term of the majorant vanishes. We have (for $\beta = 0$)

$$\mathcal{M} = \int_0^1 c^2(x - 1/2)^2 \, dx = c^2/12.$$ 

We observe that both the global error and the error distribution are exactly reproduced. In real life computations such an "ideal" function $y$ may be unattainable. However, the minimization makes the Majorant close to the sharp value. In this elementary example, we have minimized the Majorant on using piecewise affine approximations of $y$ on 20 subintervals. The elementwise error distribution obtained as the result of this procedure is exposed on the next picture.
True errors and those computed by the Majorant.
To give further illustrations, we consider the functions

$$u_\delta = u + \delta \varphi,$$

where $\delta$ is a number and $\varphi$ is a certain function (perturbation).

Approximate solutions (whose errors are measured) are piecewise affine continuous interpolants of $u_\delta$ defined on a uniform mesh with 20 subintervals. We take $\varphi = x \sin(\pi x)$ and $\delta = 0.1$, 0.01, 0.001, and 0.

Task 6

Apply the above theory to the problem

\[(\alpha u')' = f,\]
\[u(0) = 0, \quad u(1) = b\]

with your own \(\alpha, f,\) and \(b\). Compute approximate solutions and verify their accuracy along the same lines as in the example above.
Other examples

For problems with lower terms it is easy to obtain estimates without $C_\Omega$.

$$\Delta u - \varrho u + f = 0, \quad \varrho > 0,$$

$$u = u_0 \quad \text{on } \partial \Omega.$$  

Such estimates can be derived by both variational and non-variational method. Let $w \in V_0 := H^1(\Omega)$. We have

$$\int_\Omega \nabla (u - v) \cdot \nabla w \, dx + \varrho \int_\Omega (u - v)w \, dx =$$

$$= \int_\Omega (fw - \nabla v \cdot \nabla w) \, dx - \varrho \int_\Omega vw \, dx.$$
Use the integral identity for $y \in H(\Omega, \text{div})$:

$$\int_{\Omega} (\nabla w \cdot y + w \text{div} y) \, dx = 0 \quad \forall w \in V_0.$$ 

$$\int_{\Omega} \nabla(u - v) \cdot \nabla w \, dx + \varrho \int_{\Omega} (u - v) w \, dx =$$

$$\int_{\Omega} (f + \text{div} y - \varrho v) w \, dx + \int_{\Omega} (y - \nabla v) \cdot \nabla w \, dx \leq$$

$$\leq \|f + \text{div} y - \varrho v\| \|w\| + \|\nabla v - y\| \|\nabla w\|.$$
Set $\mathbf{w} = \mathbf{u} - \mathbf{v}$ and note that

$$
\| \mathbf{f} + \text{div} \mathbf{y} - \varrho \mathbf{v} \| \| \mathbf{u} - \mathbf{v} \| + \| \nabla \mathbf{v} - \mathbf{y} \| \| \nabla (\mathbf{u} - \mathbf{v}) \| = \\
= \frac{1}{\varrho} \| \mathbf{f} + \text{div} \mathbf{y} - \varrho \mathbf{v} \| \varrho \| \mathbf{u} - \mathbf{v} \| + \| \nabla \mathbf{v} - \mathbf{y} \| \| \nabla (\mathbf{u} - \mathbf{v}) \| \leq \\
\leq \left( \frac{1}{\varrho^2} \| \mathbf{f} + \text{div} \mathbf{y} - \varrho \mathbf{v} \|^2 + \| \nabla \mathbf{v} - \mathbf{y} \|^2 \right)^{1/2} \| \mathbf{u} - \mathbf{v} \|
$$

where

$$
\| \mathbf{u} - \mathbf{v} \|^2 = \int_\Omega (|\nabla (\mathbf{u} - \mathbf{v})|^2 + \varrho |\mathbf{u} - \mathbf{v}|^2) \, dx.
$$
Then, we obtain the estimate

\[ \| u - v \|^2 \leq \frac{1}{\varrho^2} \| f + \text{div}y - \varrho v \|^2 + \| \nabla v - y \|^2 \]

By the variational method this estimate was derived in 97’. Also, it readily follows from the general a posteriori framework (see, e.g., S.R. Math. Comp. 2000).

This estimate has no \( C_\Omega \). However, in practice, it may give big overestimation if \( \varrho \) is small due to large penalty at the first term.
How Functional A Posteriori Estimate looks like for the problem

$$\text{div}A \nabla u + f = 0, \quad u = u_0 \quad \text{on } \partial \Omega$$

and for problems with boundary conditions of other types?
For the generalized diffusion equation it is as follows:

\[ \| \nabla (u - v) \|^2 \leq \sqrt{D(\nabla v, y)} + C(\Omega, A) \| \text{div} y + f \|, \]

where

\[ \| \eta \|^2 := \int_\Omega A \nabla \eta \cdot \nabla \eta \, dx, \]

\[ D(\nabla v, y) := \int_\Omega (A \nabla v \cdot \nabla v + A^{-1} y \cdot y - 2 \nabla v \cdot y) \, dx = \int_\Omega (A \nabla v - y) \cdot (\nabla v - A^{-1} y) \, dx, \]

\[ \| w \| \leq C(\Omega, A) \| \nabla w \|. \]
How such estimates are derived we will discuss in the next Lecture.
We expose the general approach to deriving two-sided functional estimates of the deviations from exact solutions of linear elliptic type problems having the operator form

\[ \Lambda^* A \Lambda u + \ell = 0 \]

where \( \Lambda \) and \( A \) are linear bounded operators and \( A \) is symmetric and positive definite.
Lecture plan

- Two–sided a posteriori estimates for linear elliptic type problems;
- Properties: computability, consistency, reliability;
- Relationships with other error estimation methods;
- Diffusion equation with Dirichlét boundary conditions;
- Diffusion equation with Neumann boundary conditions;
- Diffusion equation with mixed boundary conditions;
- Linear elasticity with mixed boundary conditions;
Problem in the abstract form

Many problems can be presented in the following form: find $u \in V_0 + u_0$ such that

$$(\mathcal{A} \Lambda u, \Lambda w) + \langle \ell, w \rangle = 0 \quad \forall w \in V_0.$$ (66)

Here $V_0$ is a subspace of a reflexive Banach space $V$, e.g., $V = H^1$, $V_0 = \overset{0}{H^1}$.

$\Lambda : V \to U$ is a bounded linear operator, e.g. $\Lambda = \nabla$.

$U$ is a Hilbert space with scalar product $(\cdot, \cdot)$ and norm $\| \cdot \|$, e.g., $U = L^2$.

$\ell \in V_0^*$, is a linear functional in the dual space, e.g., in $H^{-1}$. In general, we may assume that

$$\langle \ell, w \rangle = (f, w) + (g, \Lambda w).$$

$A \in \mathcal{L}(U, U)$ is a self-adjoint operator.
Assumptions

We assume that

$$\mathbf{V} \text{ is compactly embedded in } \mathbf{U} \tag{67}$$

and the operators $\Lambda$ and $\mathcal{A}$ satisfy the relations

$$c_1 \|y\|^2 \leq (\mathcal{A}y, y) \leq c_2 \|y\|^2, \quad \forall y \in \mathbf{U}, \tag{68}$$

$$\|\Lambda w\| \geq c_3 \|w\|_V, \quad \forall w \in \mathbf{V}_0, \tag{69}$$
For our analysis, it is convenient to introduce two more norms:

\[ \| y \| := (\mathcal{A} y, y)^{1/2}, \quad \| y \|_* := (\mathcal{A}^{-1} y, y)^{1/2}, \]

where \( \mathcal{A}^{-1} : U \to U \) is the operator inverse to \( \mathcal{A} \). The respective spaces \( Y \) and \( Y^* \) contain elements of \( U \) equipped with the norms \( \| \cdot \| \) and \( \| \cdot \|_* \), respectively. Let \( \Lambda^* \) be the operator conjugate to \( \Lambda \), i.e.,

\[ (y, \Lambda w) = \langle \Lambda^* y, w \rangle, \quad \forall w \in V_0. \]  

(70)
Getting a posteriori estimates by transformations of integral identities

Let $v \in V_0 + u_0$ be an approximation.

\[(\mathcal{A}\Lambda(u - v), \Lambda w) + \langle \ell, w \rangle + (\mathcal{A}\Lambda v, \Lambda w) = 0 \quad \forall w \in V_0,\]
Set $w = u - v$.

$$
\| \Lambda(u - v) \|^2 = | \langle \ell, u - v \rangle + (A\Lambda v, \Lambda(u - v)) | .
$$

By

$$(y, \Lambda w) = \langle \Lambda^* y, w \rangle, \quad \forall w \in V_0.$$

we have

$$
\| \Lambda(u - v) \|^2 = | \langle \ell, u - v \rangle + (A\Lambda v - y, \Lambda(u - v)) + \langle \Lambda^* y, u - v \rangle | .
$$
Therefore, we find that

\[
\| \Lambda(u - v) \|^2 \leq | \langle \ell + \Lambda^* y, u - v \rangle | + | (A\Lambda v - y, \Lambda(u - v)) | \leq \\
\leq \| \ell + \Lambda^* y \| \| \Lambda(u - v) \| + \| A\Lambda v - y \| + \| \Lambda(u - v) \|,
\]

where

\[
\| \mu \| := \sup_{w \in V_0} \frac{\langle \mu, w \rangle}{\| \Lambda w \|}
\]

denotes the norm of the functional \( \mu : V_0 \to \mathbb{R} \).

To prove that the value of \( \| \ell + \Lambda^* y \| \) is finite we note that

\[
\langle \ell + \Lambda^* y, w \rangle \leq \| \ell \|_{V_0^*} \| w \|_V + \| y \| \| \Lambda w \| \leq (c_3^{-1} \| \ell \|_{V_0^*} + \| y \|) \| \Lambda w \| \leq \\
\leq c_1^{-1/2} (c_3^{-1} \| \ell \|_{V_0^*} + \| y \|) \| \Lambda w \|.
\]
General estimate

As a result we obtain the general form of a functional a posteriori estimate for an elliptic type problem:

\[
\| \Lambda (u - v) \| \leq \| \ell + \Lambda^* y \| + \| \mathcal{A} \Lambda v - y \|_*. 
\]  

(71)
Denote

\[ D(y_1, y_2) := \frac{1}{2} (Ay_1, y_1) + \frac{1}{2} (A^{-1}y_2, y_2) - (y_1, y_2) = \]

\[ = \frac{1}{2} (A(y_1 - A^{-1}y_2), y_1 - A^{-1}y_2) = \frac{1}{2} \| y_1 - A^{-1}y_2 \|^2 = \]

\[ = \frac{1}{2} (A^{-1}(y_2 - Ay_1), y_2 - Ay_1) = \frac{1}{2} \| y_2 - Ay_1 \|^2 \]

Then

\[ \| A\Lambda v - y \|^2 = 2D(\Lambda v, y) \]

and we obtain
\[ \| \Lambda(u - v) \| \leq \| \ell + \Lambda^* y \| + \sqrt{2D(\Lambda v, y)}. \]

Square both sides and use Young’s inequality

\[ \| \Lambda(u - v) \|^2 \leq \left( 1 + \frac{1}{\beta} \right) \| \ell + \Lambda^* y \|^2 + 2(1 + \beta)D(\Lambda v, y). \]  

(72)

This estimate holds for any \( y \in Y^* \) and \( \beta > 0 \). Denote its right–hand side by \( 2M_\oplus(v, \beta, y) \)
$2\mathcal{M}_\oplus(\mathbf{v}, \beta, \mathbf{y})$ is a sharp upper bound

**Proposition**

For any $\beta > 0$ there exists $\mathbf{y} \in \mathbf{Y}^*$ such that

$$2\mathcal{M}_\oplus(\beta, \mathbf{v}, \mathbf{y}) = \|\Lambda (\mathbf{u} - \mathbf{v})\|^2.$$

**Proof.** Set $\mathbf{y}_1 = \frac{1}{1+\beta} (\mathbf{p} + \beta \Lambda \mathbf{v})$ where $\mathbf{p} = \Lambda \mathbf{u}$. Note that

$$\langle \ell + \Lambda^* \mathbf{y}_1, \mathbf{w} \rangle = (-\mathbf{p} + \mathbf{y}_1, \Lambda \mathbf{w}).$$

$$\|\ell + \Lambda^* \mathbf{y}_1\| = \sup_{\mathbf{w} \in \mathbf{V}_0} \frac{(\mathbf{y}_1 - \mathbf{p}, \Lambda \mathbf{w})}{\|\Lambda \mathbf{w}\|} = \frac{\beta}{1+\beta} \sup_{\mathbf{w} \in \mathbf{V}_0} \frac{(\Lambda \Lambda (\mathbf{v} - \mathbf{u}), \Lambda \mathbf{w})}{\|\Lambda \mathbf{w}\|} = \frac{\beta}{1+\beta} \|\Lambda (\mathbf{v} - \mathbf{u})\|,$$
Similarly

\[ D(\Lambda v, y_1) = \frac{1}{2(1+\beta)^2} \| \Lambda(v - u) \|^2. \]

Therefore,

\[
\left(1 + \frac{1}{\beta}\right) [\|\ell + \Lambda^* y\|^2 + 2(1 + \beta)D(\Lambda v, y) = \\
\left(1 + \frac{1}{\beta}\right) \left(\frac{\beta}{1+\beta} \| \Lambda(v - u) \| \right)^2 + 2(1 + \beta)\left(\frac{1}{2(1+\beta)^2} \| \Lambda(v - u) \|^2 \right) = \\
= \frac{\beta}{1+\beta} \| \Lambda(v - u) \|^2 + \frac{1}{1+\beta} \| \Lambda(v - u) \|^2 = \| \Lambda(v - u) \|^2. 
\]
We replace $\| \ell + \Lambda^*y \|$ by the norm in a Hilbert space $U$ provided that $\ell$ belongs to a narrower set. Assume that

$$\ell \in U \subset V_0^*,$$

$$y \in Q^* := \{ z^* \in Y^* | \Lambda^*z^* \in U \}.$$ 

Note that $Q^*$ can be endowed with the norm

$$\| y \|_{Q^*}^2 := \| y \|_{V_0^*}^2 + \| \Lambda^*y \|_U^2.$$ 

If $\ell \in U$, then $Q^*$ contains the exact solution $p$ of the dual problem! This fact is important for the proof of the sharpness of the Majorant.
Then

\[ \langle \ell + \Lambda^* y, w \rangle = (\ell + \Lambda^* y, w) \quad w \in V_0. \]

\[ \| \ell + \Lambda^* y \| \leq \sup_{w \in V_0} \langle \ell + \Lambda^* y, w \rangle \leq \sup_{w \in V_0} \| \ell + \Lambda^* y \| \| w \| \leq \| \ell + \Lambda^* y \| c_1^{-1} \| w \| \leq c_1^{-1} c_3^{-1} \| \ell + \Lambda^* y \|. \]

Denote \( c^2 = c_1^{-2} c_3^{-2} \).
Computable Majorant of the deviation

Now, the Majorant $\mathcal{M}_\oplus$ is replaced by $\mathcal{M}_\oplus$, namely we arrive at the estimate

$$\frac{1}{2} \left\| \Lambda(v - u) \right\|^2 \leq \mathcal{M}_\oplus(v, \beta, y) :=$$

$$:= (1 + \beta)D(\Lambda v, y) + \frac{1 + \beta}{2\beta} c^2 \| \ell + \Lambda^* y \|^2. \quad (73)$$
**Problem $\mathcal{P}$.** Find $u \in V_0 + u_0$ such that

$$J(u) = \inf_{v \in V_0 + u_0} J(u) := \inf \mathcal{P},$$

where

$$J(v) = \frac{1}{2} \| \Lambda v \|^2 + \langle \ell, v \rangle.$$
On the set \((V_0 + u_0) \times Y^*\), we define the Lagrangian

\[
L(v, y) = (y, \Lambda v) - \frac{1}{2} \| y \|^2 + \langle \ell, v \rangle
\]

and the functional

\[
I^*(y) = \inf_{v \in V_0 + u_0} L(v, y) = \begin{cases} 
(y, \Lambda u_0) - \frac{1}{2} \| y \|^2 + \langle \ell, u_0 \rangle, & y \in Q^*_\ell, \\
-\infty, & y \notin Q^*_\ell,
\end{cases}
\]

where \(Q^*_\ell := \{y \in Y^* \mid (y, \Lambda w) + \langle \ell, w \rangle = 0, \quad \forall w \in V_0\}\).

Note that since

\[
(y, \Lambda (u_0 + w) + \langle \ell, (u_0 + w) \rangle) = (y, \Lambda u_0) + \langle \ell, u_0 \rangle
\]

we see that \(I^*\) does not depend on the form of \(u_0\) inside \(\Omega\).
The problem dual to $\mathcal{P}$ is as follows.

**Problem $\mathcal{P}^*$.** Find $p \in Q_\ell^*$ such that

$$I^*(p) = \sup_{y \in Q_\ell^*} I^*(y) := \sup \mathcal{P}^* \leq \inf \mathcal{P}.$$ 

The minimizer $u$ and the maximizer $p$ satisfy the conditions

$$(A \Lambda u, \Lambda w) + \langle \ell, w \rangle = 0 \quad \forall w \in V_0,$$

$$(\Lambda u_0 - A^{-1} p, y) = 0, \quad \forall y \in Q_0^*,$$

where $Q_0^* := \{ y \in Y^* \mid (y, \Lambda w) = 0, \quad \forall w \in V_0 \}.$

We see that $A \Lambda u \in Q_\ell^*$. 
Take

$$I^*(A\Lambda u) = (A\Lambda u, \Lambda u_0) - \frac{1}{2} \|A\Lambda u\|^2_2 + \langle \ell, u_0 \rangle.$$ 

Recall that the dual functional does not depend on $u_0$ inside $\Omega$. Therefore, we set $u_0 = u$ and observe that

$$I^*(A\Lambda u) = (A\Lambda u, \Lambda u) - \frac{1}{2} \|A\Lambda u\|^2_2 + \langle \ell, u \rangle \leq \sup P^*.$$ 

Since $\|A\Lambda u\|^2_2 = (A^{-1}A\Lambda u, A\Lambda u) = \|\Lambda u\|^2$, we see that

$$I^*(A\Lambda u) = J(u) = \inf P$$

Thus

$$\sup P^* = \inf P$$
The relation \( I^*(p) = J(u) \) means that

\[
(p, \Lambda u) - \frac{1}{2} \| p \|^2_* + \langle \ell, u \rangle = \frac{1}{2} \| \Lambda u \|^2 + \langle \ell, u \rangle,
\]

which is equivalent to the relation

\[
D(\Lambda u, p) = \frac{1}{2} \| \Lambda u \|^2 + \frac{1}{2} \| p \|^2_* - (p, \Lambda u) = 0.
\]

From the above we see that \( \Lambda u \) and \( p \) are joined by a certain relation:

\[
p = A\Lambda u
\]

This is the so-called \textit{duality relation} for the pair \((u, p)\).
Let $v \in V_0 + u_0$ and $y \in Y^*$ be some approximations of $u$ and $p$, respectively. Our goal is to obtain two-sided estimates of the quantities $\| \Lambda(v - u) \|$ and $\| y - p \|_*$ that are norms of deviations from the exact solutions $u$ and $p$.

First, we establish the following basic result.

**Theorem**

*For any $v \in V_0 + u_0$ and $q \in Q^*_\ell$,*

\[ \| \Lambda(v - u) \|^2 + \| q - p \|_*^2 = 2(J(v) - I^*(q)), \tag{74} \]

\[ \| \Lambda(v - u) \|^2 + \| q - p \|_*^2 = 2D(\Lambda v, q). \tag{75} \]
Proof

By the stationarity relations, we have

\[
\frac{1}{2} \| \Lambda (v - u) \|^2 = \frac{1}{2} (A \Lambda (v - u), \Lambda (v - u)) = J(v) - J(u) + \\
+ (A \Lambda u, \Lambda (u - v)) + \langle \ell, u - v \rangle = \\
= J(v) - J(u).
\]

Analogously

\[
\frac{1}{2} \| q - p \|^2 = \frac{1}{2} (A^{-1} (p - q), p - q) = \\
= l^*(p) - l^*(q) - (\Lambda u_0 - A^{-1} p, p - q) = l^*(p) - l^*(q).
\]

Since \( J(u) = l^*(p) \), we sum two relations and obtain (74). For \( q \in Q^{\ell} \) the difference \( J(v) - l^*(q) \) is equal to \( D(\Lambda v, q) \), so that (75) follows from (74).
The estimates (74) and (75) are valid only for $q \in Q_\ell^*$, which poses some difficulties. Below it is shown how we can overcome this drawback. First, we establish one subsidiary result.

**Theorem**

*Let $q \in Q_\ell^*$, $v \in V_0 + u_0$, $\beta \in \mathbb{R}_+$, and $y \in Y^*$. Then*

$$J(v) - I^*(q) \leq (1 + \beta)D(\Lambda v, y) + \frac{1 + \beta}{2\beta} \| q - y \|_*^2. \quad (76)$$

Note that

$$D(\Lambda v, y) = \frac{1}{2} (\mathcal{A} \Lambda v, \Lambda v) + \frac{1}{2} (\mathcal{A}^{-1} p, p) - (y, \Lambda u) =$$

$$= (\mathcal{A} \Lambda v - y), \Lambda v - A^{-1} y) =$$

$$= (\mathcal{A}(\Lambda v - A^{-1} y, \Lambda v - A^{-1} y) = \| \Lambda v - A^{-1} y \|. \quad (76)$$
Proof

For any \( y \in Y^* \), we have

\[
J(v) - I^*(q) = \frac{1}{2} \left( \| \Lambda v \|^2 + \| y \|^2_* \right) + \frac{1}{2} \left( \| q \|^2_* - \| y \|^2_* \right) - (\Lambda u_0, q) + \langle \ell, v - u_0 \rangle.
\]

Since \( \langle \ell, v - u_0 \rangle = (q, \Lambda(u_0 - v)) \), we find that

\[
J(v) - I^*(q) = \frac{1}{2} \left( \| \Lambda v \|^2 + \| y \|^2_* \right) + \frac{1}{2} \left( \| q \|^2_* - \| y \|^2_* \right) - (q, \Lambda v) =
\]

\[
= D(\Lambda v, y) + (y - q, \Lambda v - A^{-1}y) + \frac{1}{2} \| q - y \|^2_*.
\]

This relation yields (76) if we use the Young’s inequality

\[
2 (y - q, \Lambda v - A^{-1}y) \leq \beta \| \Lambda v - A^{-1}y \|^2 + \beta^{-1} \| y - q \|^2_*.
\]
Another form of the estimate

Introduce the quantity
\[ d_{\ell}^2(y) := \inf_{q \in Q_{\ell}^*} \| q - y \|_*^2, \]
which is the distance to \( Q_{\ell}^* \). Then, (76) imply the estimate
\[
\frac{1}{2} \| \Lambda (v - u) \|^2 \leq (1 + \beta) D(\Lambda v, y) + \left( 1 + \frac{1}{\beta} \right) \frac{1}{2} d_{\ell}^2(y)
\]
where \( v \in V_0 + u_0 \) and \( y \in Y^* \). We rewrite this estimate as
\[
\frac{1}{2} \| \Lambda (v - u) \|^2 \leq \mathcal{M}(v, \beta), \quad \forall v \in V_0 + u_0, \quad \beta \in \mathbb{R}_+,
\]
where
\[
\mathcal{M}(v, \beta) := \inf_{y \in Y^*} \left\{ (1 + \beta) D(\Lambda v, y) + \left( 1 + \frac{1}{\beta} \right) \frac{1}{2} d_{\ell}^2(y) \right\}.
\]
Now, we proceed to finding computable upper bounds for the quantity $d_\ell$. The first step is given by

**Theorem**

$$\frac{1}{2} d_\ell^2(y) = \sup_{w \in V_0} \left\{ -\frac{1}{2} \| \Lambda w \|^2 - \langle \ell, w \rangle - (y, \Lambda w) \right\}.$$
This assertion comes from that $\inf \mathcal{P} = \sup \mathcal{P}^*$. Indeed,

\[
\frac{1}{2} d_{\ell}^2(y) = - \sup_{\eta^* \in Q^*_\ell} \left\{ - \frac{1}{2} \| y - \eta^* \|_*^2 \right\} = - \sup_{\eta^* \in Q^*_\ell - y} \left\{ - \frac{1}{2} \| \eta^* \|_*^2 \right\},
\]

where $Q^*_\ell - y := \{ \eta^* \in Y^* | \eta^* = \varphi^* - y, \varphi^* \in Q^*_\ell \}$.

In other words, $\eta^* \in Q^*_\ell - y$ if

\[
(\eta^*, \Lambda w) = - \langle \ell, w \rangle - (y, \Lambda w), \quad \forall w \in V_0.
\]

The right-hand side of this relation is a linear continuous functional. We denote it by $\ell_y$ and rewrite the relation as follows:

\[
(\eta^*, \Lambda w) + \langle \ell_y, w \rangle = 0 \quad \forall w \in V_0.
\]
Then, $Q^*_\ell - y = Q^*_\ell y$ and

$$\frac{1}{2} d^2_\ell(y) = - \sup_{\eta^* \in Q^*_\ell y} \left\{ -\frac{1}{2} \| \eta^* \|^2 \right\}.$$ 

This maximization problem is a form of Problem $\mathcal{P}^*$ if set $u_0 = 0$ and $\ell = \ell y$. Since $\sup \mathcal{P}^* = \inf \mathcal{P}$, we have

$$\frac{1}{2} d^2_\ell(y) = - \inf_{w \in V_0} \left\{ \frac{1}{2} \| \Lambda w \|^2 + \langle \ell y, w \rangle \right\} =$$

$$= - \inf_{w \in V_0} \left\{ \frac{1}{2} \| \Lambda w \|^2 + \langle \ell, w \rangle + (y, \Lambda w) \right\} =$$

$$= \sup_{w \in V_0} \left\{ -\frac{1}{2} \| \Lambda w \|^2 - \langle \ell, w \rangle - (y, \Lambda w) \right\}.$$
We arrive at the conclusion that the majorant $\mathcal{M}(v, \beta)$ has a minimax form

$$
\mathcal{M}(v, \beta) = \inf_{y \in Y^*} \sup_{w \in V_0} \left\{ (1 + \beta)D(\Lambda v, y) + \frac{1 + \beta}{\beta} \left( -(y, \Lambda w) - J(w) \right) \right\}. \quad (77)
$$

Further, we use (77) for deriving upper and lower error bounds.
Upper estimates of $\| v - u \|$.

In the relation

$$
\mathcal{M}(v, \beta) \leq (1 + \beta)D(\Lambda v, y) + \\
+ \left(1 + \frac{1}{\beta}\right) \sup_{w \in V_0} \left\{ -\frac{1}{2} \| \Lambda w \|^2 - \langle \ell, w \rangle - (y, \Lambda w) \right\},
$$

we will estimate the value of supremum. Since $\Lambda^*$ is the operator conjugate to $\Lambda$, i.e.,

$$(y, \Lambda w) = \langle \Lambda^* y, w \rangle, \quad \forall w \in V_0,$$

we have

$$
\langle \ell, w \rangle + (y, \Lambda w) = \langle \ell + \Lambda^* y, w \rangle \leq \| \ell + \Lambda^* y \| \| \Lambda w \|.
$$
Here

\[ |\ell + \Lambda^* y| := \sup_{w \in V_0} \frac{\langle \ell + \Lambda^* y, w \rangle}{||\Lambda w||} < +\infty. \]

We see that

\[
\sup_{w \in V_0} \left\{ -\frac{1}{2} \| \Lambda w \|^2 - \langle \ell, w \rangle - (y, \Lambda w) \right\} \leq \\
\leq \sup_{w \in V_0} \left\{ -\frac{1}{2} \| \Lambda w \|^2 + |\ell + \Lambda^* y| \|\Lambda w\| \right\} \leq \\
\leq \sup_{t > 0} \left\{ -\frac{1}{2} t^2 + |\ell + \Lambda^* y| t \right\} = \frac{1}{2} |\ell + \Lambda^* y|^2.
\]
Thus, we obtain

$$\frac{1}{2} \| \Lambda(v - u) \|^2 \leq (1 + \beta)D(\Lambda v, y) + \frac{1 + \beta}{2\beta} \| \ell + \Lambda^* y \|^2. \quad (78)$$
Deviation Majorant for the problem $\Lambda^* A\Lambda u + \ell = 0$

$$(\mathcal{A}\Lambda(v - u), \Lambda(v - u)) \leq$$

$$\leq (1 + \beta) \left( (\mathcal{A}\Lambda v, \Lambda v) + (\mathcal{A}^{-1}y, y) - 2(y, \Lambda v) \right) +$$

$$+ \frac{1 + \beta}{\beta} c^2 \|\ell + \Lambda^* y\|^2.$$

In the above, $v \in V_0 + u_0$, $\beta > 0$, $y \in U$. 
Theorem

For any $v \in V_0 + u_0$,

$$\frac{1}{2} \| \Lambda(u - v) \|^2 = \inf_{y \in Q^*, \beta > 0} M_\oplus(v, \beta, y).$$

If $\ell \in U$, then $p \in Q^*$ and, therefore,

$$\inf_{y \in Q^*, \beta > 0} M_\oplus(v, \beta, y) \leq M_\oplus(v, \varepsilon, p) = (1 + \varepsilon)\frac{1}{2} \| \Lambda(u - v) \|^2,$$

where $\varepsilon > 0$ may be taken arbitrarily small.

Hence, the majorant $M_\oplus$ is reliable and exact.
Lower estimates

Recall the minimax form of the Majorant

\[ \mathcal{M}(v, \beta) = \inf_{y \in Y^*} \sup_{w \in V_0} \left\{ (1 + \beta)D(\Lambda v, y) + \frac{1 + \beta}{\beta} \left( -(y, \Lambda w) - J(w) \right) \right\}. \]

Since \( \sup \inf \leq \inf \sup \), we have

\[ \mathcal{M}(v, \beta) \geq \sup_{w \in V_0} \inf_{y \in Y^*} \left\{ (1 + \beta)D(\Lambda v, y) - \left( 1 + \frac{1}{\beta} \right) \left( \frac{1}{2} \| \Lambda w \|^2 + \langle \ell, w \rangle + (y, \Lambda w) \right) \right\}. \]
Thus, for any $w \in V_0$

$$M(v, \beta) \geq \inf_{y \in Y^*} \left\{ (1 + \beta) \left( \frac{1}{2} \| y \|_*^2 - (y, \Lambda v) \right) - \left( 1 + \frac{1}{\beta} \right) (y, \Lambda w) \right\} +$$

$$+ (1 + \beta) \frac{1}{2} \| \Lambda v \|^2 - \left( 1 + \frac{1}{\beta} \right) \left( \frac{1}{2} \| \Lambda w \|^2 + \langle \ell, w \rangle \right),$$

Evidently, this estimate is also valid for the function $\beta w$, which yields

$$M(v, \beta) \geq (1 + \beta) \inf_{y \in Y^*} \left\{ \frac{1}{2} \| y \|_*^2 - (y, \Lambda(v + w)) \right\} +$$

$$+ (1 + \beta) \left( \frac{1}{2} \| \Lambda v \|^2 - \frac{\beta}{2} \| \Lambda w \|^2 - \langle \ell, w \rangle \right).$$
Note that

\[ \inf_{y \in Y^*} \left\{ \frac{1}{2} \| y \|_*^2 - (y, \Lambda(v + w)) \right\} \geq \]
\[ \geq \inf_{y \in Y^*} \left\{ \frac{1}{2} \| y \|^2_* - \| y \|_* \Lambda(v + w) \right\} = -\frac{1}{2} \| \Lambda(v + w) \|^2. \]

Thus, we obtain

\[ \mathcal{M}(v, \beta) \geq (1 + \beta) \left\{ -\frac{1}{2} \| \Lambda(v + w) \|^2 + \right\] 
\[ + \frac{1}{2} \| \Lambda v \|^2 - \frac{\beta}{2} \| \Lambda w \|^2 - \langle \ell, w \rangle \right\} = \]
\[ = (1 + \beta) \left\{ -(A \Lambda v, \Lambda w) - \frac{1 + \beta}{2} \| \Lambda w \|^2 - \langle \ell, w \rangle \right\}. \]
In

$$(1 + \beta)\left\{ -(\mathcal{A}\Lambda v, \Lambda w) - \frac{1 + \beta}{2} \| \Lambda w \|^2 - \langle \ell, w \rangle \right\}.$$  

$w$ is an arbitrary function in $V_0$. We may replace

$$w \quad \text{by} \quad \frac{w}{1 + \beta}.$$  

Such a replacement leads to the Minorant $M_{\ominus}(v, w)$ that gives a lower bound of the deviation from exact solution:

For any $w \in V_0$,

$$\frac{1}{2} \| \Lambda(v-u) \|^2 \geq -\frac{1}{2} \| \Lambda w \|^2 - (\mathcal{A}\Lambda v, \Lambda w) - \langle \ell, w \rangle$$  \hspace{1cm} (79)
Minorant is sharp

It is easy to see that

\[
\sup_{w \in V_0} M_\ominus(v, w) = \frac{1}{2} \| \Lambda(v-u) \|^2.
\]

Indeed, take \( w = u - v \).

\[
M_\ominus(v, u - v) = -\frac{1}{2} \| \Lambda(u - v) \|^2 - (A\Lambda v, \Lambda u - v) - \langle \ell, u - v \rangle.
\]

Represent the last two terms as follows:

\[
- (A\Lambda v, \Lambda(u - v)) - \langle \ell, u - v \rangle =
\]

\[
= - (A\Lambda v, \Lambda(u - v)) + (A\Lambda u, \Lambda(u - v)) =
\]

\[
= (A\Lambda(u - v), \Lambda(u - v)) = \| \Lambda(u-v) \|^2
\]

so that this choice of \( w \) gives the true error.
We outline that for the exact solution \( M_\ominus = M_\oplus = 0 \)！ Indeed, assume that \( v \) coincides with \( u \). In this case,

\[
M_\ominus(u, w) = -\frac{1}{2} \| \Lambda w \|^2 - (\Lambda \Lambda u, \Lambda w) - \langle \ell, w \rangle = -\frac{1}{2} \| \Lambda w \|^2
\]

and, therefore,

\[
\sup_{w \in V_0} M_\ominus(u, w) = 0.
\]

The same is true for the majorant. Indeed, set \( \hat{y} = \Lambda \Lambda u \). Then,

\[
M_\oplus(u, \beta, \hat{y}) = (1 + \beta)D(\Lambda u, \hat{y}) + \frac{1 + \beta}{2\beta} c^2 \| \ell + \Lambda^* \Lambda \Lambda u \|^2 = 0.
\]

Thus,

\[
\inf_{y \in Y^*} M_\oplus(u, \beta, y) = 0.
\]
Computability of two–sided estimates

By *computability* we mean that upper and lower estimates can be computed with any a priori given accuracy by solving finite-dimensional problems. In the case considered, they are certain problems for quadratic type integral functionals whose minimization (maximization) is performed by well-known methods.
Let $\{Y_i^*\}_{i=1}^{\infty}$ and $\{V_{0i}\}_{i=1}^{\infty}$ be two sequences of finite-dimensional subspaces that are dense in $Q^*$ and $V_0$, respectively, i.e., for any given $\varepsilon > 0$ and arbitrary elements $y \in Y^*$ and $w \in V_0$, one can find a natural number $k_\varepsilon$ such that

$$\inf_{\tilde{w} \in V_{0i}} \| \tilde{w} - w \|_V \leq \varepsilon, \quad \inf_{\tilde{y} \in Y_i^*} \| \tilde{y} - y \|_{Q^*} \leq \varepsilon, \quad \forall \ i \geq k_\varepsilon.$$ 

Let us show that sequences of two-sided bounds converging to the actual error can be evaluated by minimizing the Majorant on $\{Y_i^*\}$ and maximizing the Minorant on $\{V_{0i}\}$. 
Take a small $\varepsilon > 0$. Then there exists a number $k$ and elements $w_k \in V_{0k}$ and $p_k \in Y_{0k}^*$ satisfying the conditions

$$\|w_k - (u - v)\|_V \leq \varepsilon, \quad \|p_k - p\|_{Q^*} \leq \varepsilon.$$

Define two quantities defined by solving finite–dimensional problems, namely

$$M_k^\oplus = \inf_{y_k \in Y_{0k}^*, \beta \in \mathbb{R}^+} M_\oplus(v, \beta, y_k), \quad M_k^\ominus = \sup_{w_k \in V_{0k}} M_\ominus(v, w_k).$$

By the definition

$$M_\ominus(v, w_k) \leq M_k^\ominus \leq \frac{1}{2} \|u - v\|^2 \leq M_k^\oplus \leq M_\oplus(v, \beta, p_k).$$
The quantities $M^k_\ominus$ and $M^k_\oplus$ are \textbf{computable} (they require solving finite dimensional problems for quadratic type functionals). We will that

\[
M^k_\ominus \rightarrow \frac{1}{2} \| \Lambda (v - u) \|^2,
\]

\[
M^k_\oplus \rightarrow \frac{1}{2} \| \Lambda (v - u) \|^2
\]
as the dimensionality $k$ tends to $+\infty$. 
Consider the upper estimates.

\[ M_\oplus(v, \beta, p_k) = (1 + \beta)D(\Lambda v, p_k) + \frac{1 + \beta}{2\beta} c^2 \| \ell + \Lambda^* p_k \|^2 = \]

\[ = (1 + \beta)D(\Lambda v, p_k) + \frac{1 + \beta}{2\beta} c^2 \| \Lambda^*(p_k - p) \|^2. \]

Here

\[ D(\Lambda v, p_k) = \frac{1}{2} (\Lambda v - A^{-1} p_k, A\Lambda v - p_k) = \]

\[ = \frac{1}{2} \left( \Lambda(v - u) - A^{-1}(p_k - p), A\Lambda(v - u) - (p_k - p) \right) = \]

\[ = \frac{1}{2} \| \Lambda(v - u) \|^2 + \| p_k - p \|_*^2 - (\Lambda(v - u), p_k - p). \]

From the latter estimate we see that

\[ D(\Lambda v, p_k) \leq \frac{1}{2} \| \Lambda(v - u) \|^2 + \epsilon \| \Lambda(v - u) \| + \frac{1}{2} \epsilon^2. \quad (80) \]
Since

\[ \| \Lambda^*(p_k - p) \|_{Q^*} \leq \varepsilon, \]

we find that

\[ M_k^\square \leq M_\oplus(v, \varepsilon, p_k) = \]

\[ = (1 + \varepsilon) \left( \frac{1}{2} \| \Lambda(v - u) \|^2 + \varepsilon \| \Lambda(v - u) \| + \frac{1}{2} \varepsilon^2 \right) + \frac{1 + \varepsilon}{2\varepsilon} c^2 \varepsilon^2 = \]

\[ = \frac{1}{2} \| \Lambda(v - u) \|^2 + c_4 \varepsilon + o(\varepsilon^2). \]

where \( c_4 = \frac{1}{2} (c + 2 \| \Lambda(v - u) \| + \| \Lambda(v - u) \|^2) \). Thus, we conclude that

\[ M_k^\square \longrightarrow \frac{1}{2} \| \Lambda(v - u) \|^2 \quad \text{as} \quad k \rightarrow \infty. \]
Remark

It is worth noting that the constant $c_4$ in the convergence term with $\varepsilon$ depends on the norm of $(v - u)$, so that we can await that for a good approximation convergence of the upper bounds to the exact value of the error is faster than in the case where $\|v - u\|$ is considerable. This phenomenon was observed in many numerical experiments. In general, finding an upper bound for a precise approximation takes less CPU time than for a coarse one.
Consider the lower estimates.

\[ M_{\Theta}(v, w_k) = -\frac{1}{2} \| \Lambda w_k \|^2 - (\mathcal{A}\Lambda v, \Lambda w_k) - \langle \ell, w_k \rangle = \]
\[ = -\frac{1}{2} \| \Lambda w_k \|^2 + (\mathcal{A}\Lambda(u - v), \Lambda w_k) = \]
\[ = \frac{1}{2} \| \Lambda(u - v) \|^2 - \frac{1}{2} \| \Lambda(w_k - (u - v)) \|^2 \geq \]
\[ \geq \frac{1}{2} \| \Lambda(u - v) \|^2 - \frac{1}{2} c_2 \| \Lambda(w_k - (u - v)) \|^2. \]

This implies the estimate

\[ \frac{1}{2} \| \Lambda(u - v) \|^2 \geq M^k_{\Theta} \geq \frac{1}{2} \| \Lambda(u - v) \|^2 - c_5 \varepsilon^2, \]

where \( c_5 > 0 \) depends on the norm of \( \Lambda \). Thus,

\[ M^k_{\Theta} \rightarrow \frac{1}{2} \| \Lambda(u - v) \|^2 \quad \text{as} \quad k \rightarrow \infty. \]
Computable upper bound of the effectivity index

Having $M_k^\oplus$ and $M_k^\ominus$, one can define the number

\[
\eta_k := \frac{M_k^\oplus}{M_k^\ominus} \geq 1, \quad (81)
\]

which gives an idea of the quality of the error estimation. From the above it follows that

\[
\eta_k \to 1, \quad \text{as } k \to +\infty.
\]
Relationships with other methods

\[ M_\oplus(v, \beta, y) = (1 + \beta)D(\Lambda v, y) + \frac{1 + \beta}{2\beta} c^2 \| \ell + \Lambda^* y \|^2 \]

involves an arbitrary function \( y \). We are aimed to show that some special choices of it lead to known error estimates.

We assume that \( \langle \ell, w \rangle = (g, w) \), where \( g \in U \), so that \( p \in Q^* \subset Q^*_\ell \) and

\[ Q^*_\ell := \{ y \in Q^* \mid (\Lambda^* y + g, w) = 0, \quad \forall w \in V_0 \}. \]
Let us first define the function

\[ y_0 = \mathcal{A} \Lambda v. \]  

(82)

A variety of options comes from the relation

\[ y = \Pi y_0, \]  

(83)

where \( \Pi \) is a certain continuous mapping.
Residual based estimate

If \( \Pi \) is the identity mapping of \( Y^* \), i.e., \( y = y_0 := A \Lambda v \), then

\[
D(\Lambda v, y_0^*) = 0.
\]

Use the majorant in the form (78):

\[
\frac{1}{2} \left\| \Lambda(v - u) \right\|^2 \leq (1 + \beta)D(\Lambda v, y) + \frac{1 + \beta}{2\beta} \left[ \ell + \Lambda^*y \right]^2.
\]

Now, it contains only the second term, which after the minimization with respect to \( \beta \) gives

\[
\left\| \Lambda(v - u) \right\| \leq \left[ \ell + \Lambda^*A\Lambda v \right] = \sup_{w \in \mathcal{V}_0} \frac{(\ell, w) + (A\Lambda v, \Lambda w)}{\left\| \Lambda w \right\|}. \tag{84}
\]
If $v$ is obtained by FEM and $v = u_h \in V_h := V_{0h} + u_0$, then we arrive at the following estimate:

$$\| \Lambda (u_h - u) \| \leq \| \ell + \Lambda^* A \Lambda u_h \| =$$

$$\sup_{w \in V_0} \frac{(\ell, w - w_h) + (A \Lambda u_h, \Lambda (w - w_h))}{\| \Lambda w \|}.$$

We find an upper bound of the right-hand side by the arguments accepted in the classical residual method.
Conclusion

If in the functional a posteriori error estimate is applied to a FEM solution $u_h$ then we may select the variable $y$ in the simplest way as

$$y = \Lambda u_h.$$  

Then, if $u_h$ is a Galerkin approximation, we can use this fact and obtain at an upper bound given by the *residual type a posteriori error estimate* that involves integral terms associated with finite elements and interelement jumps.
Estimates using post–processing of the dual variable

In $M_\oplus(v, \beta, y)$ the best choice is $y = p \in Q^*$. Therefore, if $y_0 \not\in Q^*$ then its mapping $Q^*$ could be a better approximation of $p$. Let us denote such a mapping by $\Pi_1$. We obtain

$$y_1 = \Pi_1 y_0 \in Q^*$$

and the quantity $M_\oplus(v, \beta, y_1)$, which leads to the error majorant

$$M^{(1)}_\oplus(v) = \inf_{\beta \in \mathbb{R}_+} \left\{ (1 + \beta) D(\Lambda v, \Pi_1(\mathcal{A}\Lambda v)) + \frac{1 + \beta}{2 \beta} c^2 \| \ell + \Lambda^* \Pi_1(\mathcal{A}\Lambda v) \|^2 \right\}.$$
Particular case

In the simplest case associated with the problem

\[ \Delta u + f = 0, \quad u = u_0 \quad \text{on} \quad \partial \Omega \]

we have

\[
M^{(1)}_\oplus(u_h) = \\
= \inf_{\beta \in \mathbb{R}_+} \left\{(1 + \beta)\|\nabla u_h - \Pi_1(\nabla u_h)\|^2 + \frac{(1 + \beta)C^2_\Omega}{2\beta} \|f + \text{div}\Pi_1(\nabla u_h)\|^2\right\}.
\]

If \( \Pi_1 \) is a gradient averaging operator, then the first term in the right-hand side is the difference between the original and averaged gradient, i.e. it coincides with a gradient averaging indicator. However, as we have seen in previous lectures, such an indicator cannot provide a reliable upper bound of the error. The second term in the right-hand side shows what is necessary to add in order to provide the reliability.
Estimates based on the "equilibration" of the dual variable

Let $\Pi_2$ maps $Y^*$ to the set $Q_\ell^*$. Define

$$y_2 = \Pi_2 y_0 \in Q_\ell^*. \quad (87)$$

Then,

$$\Lambda^* y_2 + \ell = 0,$$

so that the Majorant has only the first term:

$$M^{(2)}_\oplus(v) = D(\Lambda v, y_2).$$

$\Pi_2$ is natural to call an equilibration operator. In general, it is rather difficult to construct an "exact mapping" $\Pi_2$ to $Q_\ell^*$. One may use an operator $\tilde{\Pi}_2$, which provides an approximate "equilibration". In this case, the second term of the Majorant does not vanish and should be taken into account.
Various choices of the dual variable lead to certain a posteriori methods.
A priori projection type error estimates

As an exercise, we now will derive classical a priori projection type error estimates from a functional a posteriori estimate. Let \( u_h \in V_h \) be a Galerkin approximation of \( u \). We have

\[
\| \Lambda(u - u_h) \|^2 \leq 2(1 + \beta)D(\Lambda u_h, y) + \left(1 + \frac{1}{\beta}\right) I \Lambda^* y + \ell I^2
\]

Set here \( y = A\Lambda v_h \), where \( v_h \) is an arbitrary element of \( V_h \). Then,

\[
I \Lambda^* y + \ell I = \sup_{w \in V_0} \frac{(y - p, \Lambda w)}{\| \Lambda w \|} = \sup_{w \in V_0} \frac{(A\Lambda(v_h - u), \Lambda w)}{\| \Lambda w \|} \leq \| \Lambda(v_h - u) \|.
\]
It is easy to see that

$$D(\Lambda u_h, A\Lambda v_h) = J(v_h) - J(u_h).$$

Indeed,

$$D(\Lambda u_h, A\Lambda v_h) = \frac{1}{2} (A\Lambda v_h, \Lambda v_h) + \langle \ell, v_h \rangle -$$

$$- \frac{1}{2} (A\Lambda u_h, \Lambda u_h) - \langle \ell, u_h \rangle +$$

$$+ (A\Lambda u_h, \Lambda(u_h - v_h)) + \langle \ell, u_h - v_h \rangle.$$

Since $u_h \in V_h$ is a Galerkin approximation, the last two terms vanish and we obtain the relation.

We know that

$$\| \Lambda(u_h - u) \|^2 = 2(J(u_h) - J(u)),$$

$$\| \Lambda(v_h - u) \|^2 = 2(J(v_h) - J(u)).$$
Therefore,

\[ 2D(\Lambda u_h, A\Lambda v_h) = 2(J(v_h) - J(u)) - 2(J(u_h) - J(u)) = \]
\[ = \| \Lambda (v_h - u) \|^2 - \| \Lambda (u_h - u) \|^2. \]

Now, the error estimate comes in the form

\[ \| \Lambda (u - u_h) \|^2 \leq (1 + \beta) (\| \Lambda (v_h - u) \|^2 - \| \Lambda (u_h - u) \|^2) + \]
\[ + \left(1 + \frac{1}{\beta}\right) \| \Lambda (v_h - u) \|^2. \]

Thus, we obtain

\[ (2 + \beta) \| \Lambda (u - u_h) \|^2 \leq \]
\[ \leq (1 + \beta) \| \Lambda (v_h - u) \|^2 + \left(1 + \frac{1}{\beta}\right) \| \Lambda (v_h - u) \|^2, \]
We see that

\[ \| \Lambda (u - u_h) \|^2 \leq \left( 1 + \frac{1}{\beta(2 + \beta)} \right) \| \Lambda (u - v_h) \|^2. \]

Since $\beta$ is an arbitrary positive number, we arrive at the projection type error estimate

\[ \| \Lambda (u - u_h) \| \leq \inf_{v_h \in V_h} \| \Lambda (u - v_h) \|. \]
APPLICATIONS TO PARTICULAR CLASSES OF PARTIAL DIFFERENTIAL EQUATIONS
**Diffusion equation**

Let $\mathcal{A}$ is produced by a matrix $\mathbf{A} = \{a_{ij}\} = \{a_{ji}\}$, $\mathbf{V} = H^1(\Omega)$, where $\Omega$ is a Lipschitz domain, $\mathbf{U} = L^2(\Omega, \mathbb{R}^n)$, and $\Lambda w = \nabla w$. Let the entries of $\mathbf{A}$ be bounded at almost all points of $\Omega$ and such that

$$c_1|\xi|^2 \leq a_{ij}\xi_i\xi_j \leq c_2|\xi|^2, \quad \forall \xi \in \mathbb{R}^n. \quad (88)$$

Then, the spaces $\mathbf{Y}$ and $\mathbf{Y}^*$ have the norms

$$\| \mathbf{y} \|^2 = \int_\Omega \mathbf{A} \mathbf{y} \cdot \mathbf{y} \, dx, \quad \| \mathbf{y} \|^2_* = \int_\Omega \mathbf{A}^{-1} \mathbf{y} \cdot \mathbf{y} \, dx.$$
Dirichlet boundary conditions

We begin with the problem

\[ \text{div} A \nabla u = f \quad \text{in} \quad \Omega, \]  
\[ u = u_0 \quad \text{on} \quad \partial \Omega. \]  

(89)  
(90)

In this case, \( V_0 = \overset{\circ}{H}^1(\Omega) \) and \( u \) meets the integral identity

\[ \int_{\Omega} A \nabla u \cdot \nabla w \, dx + \langle f, w \rangle = 0, \quad \forall w \in V_0. \]  

(91)

The relation \( (y, \Lambda w) = \langle \Lambda^* y, w \rangle \) has the form

\[ \int_{\Omega} y \cdot \nabla w \, dx = \langle -\text{div} y, w \rangle, \]

\[ \int_{\Omega} y \cdot \nabla w \, dx = \langle -\text{div} y, w \rangle, \]

where \( \Lambda^* = -\text{div} \) and \( \text{div} y \) is in \( H^{-1}(\Omega) \).
The operator \( \Lambda \) satisfies the required inequality

\[
c_\Omega \| \nabla w \| \geq \| w \|, \quad \forall w \in \overset{\circ}{H}^1(\Omega).
\]

Upper estimates of \( \| v - u \| \) for an approximation \( v \in V_0 + u_0 \) follow from the general estimate presented in Lecture 5. We have

\[
\frac{1}{2} \int_{\Omega} A \nabla(v - u) \cdot \nabla(v - u) \, dx \leq M_{\oplus}(v, \beta, y),
\]

where

\[
M_{\oplus}(v, \beta, y) =
\frac{1 + \beta}{2} \int_{\Omega} \left( \nabla v - A^{-1} y \right) \cdot \left( A \nabla v - y \right) \, dx + \frac{1 + \beta}{2\beta} \frac{c_\Omega^2}{c_1^2} \| \text{div} \, y - f \|^2
\] (92)
Certainly, the above estimate is applicable for the case $f \in L^2(\Omega)$ so that

$$\langle f, w \rangle = \int_{\Omega} fw \, dx,$$

and for $y \in H(\Omega, \text{div})$.

Let $\{Y_k^*\}$ be finite-dimensional subspaces of $Y^*$ such that

$$Y_k^* \in H(\Omega, \text{div}) \quad \text{for all } k = 1, 2, \ldots;$$

$$\dim Y_k^* \to +\infty \quad \text{as } k \to \infty.$$

We obtain computable upper bounds

$$M_k^{\oplus} = \inf_{\substack{y \in Y_k^* \setminus \mathbb{R}}} \left\{ \frac{1+\beta}{2} \int_{\Omega} \left( \nabla v - A^{-1} y \right) \cdot \left( A \nabla v - y \right) \, dx + \right.$$ 

$$+ \frac{1+\beta}{2\beta} \frac{c_2}{c_1} \| \text{div} y - f \|_{\Omega}^2 \right\}. \quad (93)$$
Lower estimates

We have

$$\frac{1}{2} \int_{\Omega} \mathbf{A} \nabla (\mathbf{v} - \mathbf{u}) \cdot \nabla (\mathbf{v} - \mathbf{u}) \, dx \geq M_{\Theta}(\mathbf{v}, \mathbf{w}), \quad \forall \mathbf{w} \in \mathbf{V}_0,$$

where

$$M_{\Theta}(\mathbf{v}, \mathbf{w}) = -\frac{1}{2} \int_{\Omega} \mathbf{A} \nabla \mathbf{w} \cdot \nabla \mathbf{w} \, dx - \int_{\Omega} \mathbf{A} \nabla \mathbf{v} \cdot \nabla \mathbf{w} \, dx - \langle f, \mathbf{w} \rangle.$$

Let \( \{ \mathbf{V}_{0k} \} \) be finite-dimensional subspaces such that

$$\mathbf{V}_{0k}^* \subset \mathbf{V}_0 \quad \text{for all } k = 1, 2, \ldots;$$
$$\dim \mathbf{V}_{0k} \to +\infty \quad \text{as } k \to \infty.$$

Find the numbers

$$M_{\Theta}^k = \sup_{\mathbf{w}_k \in \mathbf{V}_{0k}} M_{\Theta}(\mathbf{v}, \mathbf{w}_k). \quad (94)$$
Both sequences $M_k^\ominus$ and $M_k^\oplus$ tend to $\frac{1}{2} \| v - u \|^2$ as $k \to \infty$, provided that
\( \{Y^*_k\} \) and \( \{V_{0k}\} \) possess necessary approximation properties (limit density). Note that if $v$ is a Galerkin approximation computed on $V_{0k}$, then $M_\ominus(v, w_k) = 0$. This means that to obtain a sensible lower estimate in this case, one must always use a finite-dimensional subspace that is \textit{larger} than $V_{0k}$. 

Consider the Neumann boundary condition

$$\nu \cdot A \nabla u + F = 0 \quad \text{on} \quad \partial \Omega,$$

where $\nu$ is the vector of unit outward normal to $\partial \Omega$. To apply the general scheme we set

$$V_0 := \left\{ v \in H^1(\Omega) \mid \int_{\Omega} v \, dx = 0 \right\}$$

and define $\Lambda^* y \in V_0^*$ by the relation

$$\langle \Lambda^* y, w \rangle = \int_{\Omega} y \cdot \nabla w \, dx, \quad \forall w \in V_0.$$

If $y$ is sufficiently regular then

$$\langle \Lambda^* y, w \rangle = \int_{\Omega} (-\text{div} y) w \, dx + \int_{\partial \Omega} (y \cdot \nu) w \, dx.$$
Therefore, in such a case

$$\Lambda^* y = \left[ -\text{div} y \mid \Omega; \quad y \cdot \nu \mid \partial \Omega \right]$$

Also, we assume that $F$ and $f$ satisfy the equilibrium condition

$$\int_{\Omega} f \, dx + \int_{\partial \Omega} F \, dx = 0.$$ 

Assume that $f \in L^2(\Omega)$ and $F \in L^2(\partial \Omega)$. Then the Neumann problem has a solution defined by the integral identity

$$\int_{\Omega} A \nabla u \cdot \nabla w \, dx + \langle \ell, w \rangle = 0, \quad \forall w \in V_0,$$

where

$$\langle \ell, w \rangle = \int_{\Omega} f w \, dx + \int_{\partial \Omega} F w \, ds.$$
In general, \( \| \ell + \Lambda^* y \| \) is estimated in terms of the norms
\[
\| \text{div} y - f \|_{H^{-1}} \quad \text{and} \quad \| y \cdot \nu + F \|_{H^{-1/2}}.
\]
However, if we assume that \( y \) possesses a certain regularity, so that
\[
y \in Q^*(\Omega) := \{ y \in Y^* \mid \text{div} y \in L^2(\Omega), y \cdot \nu \in L^2(\partial\Omega) \},
\]
then
\[
\langle \ell + \Lambda^* y, w \rangle = \int_\Omega (f - \text{div} y) w \, dx + \int_{\partial\Omega} (F + y \cdot \nu) w \, ds
\]
and, therefore,
\[
|\langle \ell + \Lambda^* y, w \rangle| \leq \leq \| \text{div} y - f \|_{2,\Omega} \| w \|_{2,\Omega} + \| y \cdot \nu + F \|_{2,\partial\Omega} \| w \|_{2,\partial\Omega}.
\] (96)
Let the constant $c_\Omega$ be defined as

$$\frac{1}{c_\Omega^2} = \inf_{w \in V_0} \frac{\int_{\Omega} A \nabla w \cdot \nabla w \, dx}{\|w\|_{2,\Omega}^2 + \|w\|_{2,\partial\Omega}^2}.$$

Since the trace operator is bounded, this constant is finite. Therefore, (96) implies the estimate

$$|\langle \ell + \Lambda^* y, w \rangle| \leq c_{\Omega, \partial\Omega} \left( \| \text{div} \, y - f \|_{2,\Omega}^2 + \| y \cdot \nu + F \|_{2,\partial\Omega}^2 \right)^{1/2} \| \Lambda w \|^2$$

and the second term of the majorant is calculated as follows:

$$\| \ell + \Lambda^* y \| = \sup_{w \in V_0} \frac{\langle \ell + \Lambda^* y, w \rangle}{\| \Lambda w \|} \leq c_{\Omega, \partial\Omega} \left( \| \text{div} \, y - f \|_{2,\Omega}^2 + \| y \cdot \nu + F \|_{2,\partial\Omega}^2 \right)^{1/2}.$$

The term $D(\Lambda v, y)$ is defined as in the Dirichlet problem.
We see that the Majorants $\mathbf{M}_\oplus$ for the two main boundary-value problems have different values of $c_\Omega$. In addition, the Neumann problem majorant contains an extra term

$$\|y \cdot \nu + F\|_{2, \partial\Omega}$$

that penalizes violations of the Neumann boundary condition. It is worth noting that if the given $F$ can be exactly reproduced by $y \cdot \nu$ for $y$ in a certain finite dimensional subspace $Y_k^*$, then one can compute $\mathbf{M}_k^\oplus$ as

$$\mathbf{M}_k^\oplus = \inf_{\substack{y \in Y_k^*, \ y \cdot \nu = F \ 	ext{on} \ \partial\Omega \ \beta \in \mathbb{R}_+}} \left\{ \frac{1+\beta}{2} \int_\Omega (\nabla v - A^{-1}y) \cdot (A\nabla v - y) \, dx + \frac{1+\beta}{2\beta} \ c_{\Omega, \partial\Omega}^2 \| \text{div} y - f \|_{\Omega}^2 \right\}. \quad (97)$$
Mixed boundary conditions

Let $\partial \Omega$ consist of two measurable nonintersecting parts $\partial_1 \Omega$ and $\partial_2 \Omega$, on which different boundary conditions are given:

$$u = u_0 \quad \text{on} \quad \partial_1 \Omega,$$

$$\nu \cdot A \nabla u + F = 0 \quad \text{on} \quad \partial_2 \Omega.$$

Set

$$V_0 := \left\{ v \in H^1(\Omega) \mid v = 0 \quad \text{on} \quad \partial_1 \Omega \right\}$$

and

$$\langle \Lambda^* y, w \rangle = \int_{\Omega} y \cdot \nabla w \, dx, \quad \forall w \in V_0.$$
Assume that
\[ f \in L^2(\Omega), \quad F \in L^2(\partial_2 \Omega). \]
and \( y \) possesses an extra regularity, namely,
\[ y \in Q^*(\Omega) := \left\{ y \in Y^* \mid \text{div} \ y \in L^2(\Omega), \ y \cdot \nu \in L^2(\partial_2 \Omega) \right\}. \]

Then, for any \( w \subset V_0 \), we have
\[
\langle \ell + \Lambda^* y, w \rangle = \int_{\Omega} (\text{div} \ y - f) w \, dx + \int_{\partial_2 \Omega} (y \cdot \nu + F) w \, ds,
\]

Note that \( p \in Q^*(\Omega)! \)
Now, we obtain

$$|\langle \ell + \Lambda^* y, w \rangle| \leq \| \text{div} y - f \|_{2, \Omega} \| w \|_{2, \Omega} + \| y \cdot \nu + F \|_{2, \partial_2 \Omega} \| w \|_{2, \partial_2 \Omega}.$$ 

Let $\gamma$ and $\gamma^*$ be two numbers such that $\gamma > 1$, $\gamma^* > 1$, $\frac{1}{\gamma} + \frac{1}{\gamma^*} = 1$. Use the algebraic inequality

$$ab + cd \leq \sqrt{\gamma a^2 + \gamma^* c^2} \sqrt{\frac{1}{\gamma} b^2 + \frac{1}{\gamma^*} d^2}.$$ 

Then

$$|\langle \ell + \Lambda^* y, w \rangle| \leq \left( \gamma \| \text{div} y - f \|_{2, \Omega}^2 + \gamma^* \| y \cdot \nu + F \|_{2, \partial_2 \Omega}^2 \right)^{1/2} \times$$

$$\times \left( \frac{1}{\gamma} \| w \|_{2, \Omega}^2 + \frac{1}{\gamma^*} \| w \|_{2, \partial_2 \Omega}^2 \right)^{1/2}.$$
Since (Friederichs type inequality)

\[ \|w\|_{2,\Omega}^2 \leq C_F^2(\Omega) \|\nabla w\|_{2,\Omega}^2, \quad \forall w \in V_0, \]

and (trace inequality)

\[ \|w\|_{2,\partial_2\Omega}^2 \leq C_{tr}^2(\Omega, \partial_2\Omega) \|w\|_{2,\Omega}^2, \quad \forall w \in V_0, \]

we find that

\[
\frac{1}{\gamma} \|w\|_{2,\Omega}^2 + \frac{1}{\gamma_*} \|w\|_{2,\partial_2\Omega}^2 \leq \]

\[
\leq C_F^2 \frac{1}{\gamma} \|\nabla w\|_{2,\Omega}^2 + C_{tr}^2 \frac{1}{\gamma_*} \left( \|w\|_{2,\Omega}^2 + \|\nabla w\|_{2,\Omega}^2 \right) \leq \]

\[
\leq \left( C_F^2 \frac{1}{\gamma} + C_{tr}^2 \frac{1}{\gamma_*} \left( 1 + C_F^2 \right) \right) \|\nabla w\|_{2,\Omega}^2. \]
Therefore, there exist a positive constant $C_\gamma$ such that

$$\frac{1}{C^2_\gamma} = \inf_{w \in V_0} \frac{\int_{\Omega} A \nabla w \cdot \nabla w \, dx}{\frac{1}{\gamma} \|w\|_{2,\Omega}^2 + \frac{1}{\gamma^*} \|w\|_{2,\partial_2 \Omega}^2}.$$ 

The value of this constant can be estimated numerically by minimizing the above quotient on a sufficiently representative finite dimensional subspace. Besides, if $C_F$ and $C_{tr}$ are estimated, then

$$C^2_\gamma \leq \hat{C}^2_\gamma := \left( C^2_F \frac{1}{\gamma} + C^2_{tr} (1 + C^2_F) \frac{1}{\gamma^*} \right) c_1^{-1},$$

so that an upper bound of $C_\gamma$ is directly computed. Now,

$$|\langle \ell + \Lambda^* y, w \rangle| \leq \hat{C}_\gamma \left( \gamma \|\text{div} y - f\|_{2,\Omega}^2 + \gamma^* \|y \cdot \nu + F\|_{2,\partial_2 \Omega}^2 \right)^{1/2} \|\nabla w\|.$$
From this estimate, we obtain

\[ I \ell + \Lambda^* y I^2 \leq \hat{C}_2^2 \left( \gamma \| \operatorname{div} y - f \|_{2,\Omega}^2 + \frac{\gamma}{\gamma - 1} \| y \cdot \nu + F \|_{2,\partial_2\Omega}^2 \right). \]

Consider first the case, in which we simply set \( \gamma = \gamma^* = 2 \). Then

\[ \hat{C}_2^2 (\gamma = 2) := \hat{C}_2^2 = \frac{1}{2} \left( C_F^2 + C_{tr}^2 (1 + C_F^2) \right) c_1^{-1}, \]

\[ I \ell + \Lambda^* y I^2 \leq 2\hat{C}_2^2 \left( \| \operatorname{div} y - f \|_{2,\Omega}^2 + \| y \cdot \nu + F \|_{2,\partial_2\Omega}^2 \right). \]

and we find that

\[ M_\oplus (v, \beta, y) = \frac{1 + \beta}{2} \int_\Omega (\nabla v - A^{-1} y) \cdot (A \nabla v - y) \, dx + \]

\[ + \frac{1 + \beta}{2\beta} \hat{C}_2^2 \left( \| \operatorname{div} y - f \|_{2,\Omega}^2 + \| y \cdot \nu + F \|_{2,\partial_2\Omega}^2 \right). \quad (98) \]

This Majorant gives an upper bound of the deviation for any \( v \in V_0 + u_0, \) \( y \in Q^* \), and \( \beta > 0 \).
A more exact estimate is obtained if we define $\gamma$ by minimizing of the Majorant. Then, we obtain

$$\int \ell + \Lambda^* y \, I^2 \leq \left( C_F \| \text{div} \, y - f \|_{2,\Omega} + C_{\text{tr}} \left( 1 + C_F^2 \right)^{1/2} \| y \cdot \nu + F \|_{2,\partial_2 \Omega} \right)^2 c_1^{-2},$$

and

$$\mathbf{M}_\oplus(v, \beta, y) = \frac{1 + \beta}{2} \int_\Omega (\nabla v - A^{-1} y) \cdot (A \nabla v - y) \, dx +$$

$$+ \frac{1 + \beta}{2\beta} \left( C_F \| \text{div} \, y - f \|_{2,\Omega} + C_{\text{tr}} \left( 1 + C_F^2 \right)^{1/2} \| y \cdot \nu + F \|_{2,\partial_2 \Omega} \right)^2 c_1^{-2}. \quad (99)$$

Majorant vanishes if and only if $v = u$ and $y = A \nabla u$, it is continuous with respect to the convergence of $v$ in $V$ and $y$ in $Q$. 
Lower estimates

Lower estimates for the problems considered follow from the general ones obtained in the previous lecture. They have the form

\[
\frac{1}{2} \int_{\Omega} A \nabla (v - u) \cdot \nabla (v - u) \, dx \geq M_\Theta(v, w), \quad \forall w \in V_0,
\]

where

\[
M_\Theta(v, w) = -\frac{1}{2} \int_{\Omega} A \nabla (w - v) \cdot \nabla w \, dx - \int_{\Omega} fw \, dx - \int_{\partial_2 \Omega} Fw \, ds.
\]

Here \(V_0\) depends on the type of boundary conditions, and the integral over \(\partial_2 \Omega\) must be eliminated in the case of Dirichlet problem.
Linear elasticity

Classical statement. The classical formulation is as follows:

Find a tensor-valued function $\sigma^*$ (stress) and a vector-valued function $u$ (displacement) that satisfy the system of equations

\[
\begin{align*}
\sigma^* &= \mathbb{L}\varepsilon(u) \quad \text{in} \quad \Omega, \quad (\text{Hooke’s law}) \\
\text{div}\sigma^* &= f \quad \text{in} \quad \Omega, \quad (\text{Equilibrium equation}) \\
u &= u_0 \quad \text{on} \quad \partial_1\Omega, \\
\sigma^*\nu + F &= 0 \quad \text{on} \quad \partial_2\Omega.
\end{align*}
\]

where $\varepsilon(u)$ is a symmetric part of the tensor $\nabla u$. 
Here $\Omega$ is a bounded domain with Lipschitz boundary $\partial\Omega$ that consists of two disjoint parts $\partial_1 \Omega$ and $\partial_2 \Omega$, $|\partial_1 \Omega| > 0$, $f$ and $F$ are given forces and $L = \{L_{ijkl}\}$ is the tensor of elasticity constants, which is subject to the conditions

\[
C_1 |\varepsilon|^2 \leq L : \varepsilon \leq C_2 |\varepsilon|^2, \quad \forall \varepsilon \in \mathbb{M}^{n \times n}_{s},
\]

and

\[
L_{ijkl} = L_{jikl} = L_{kmij}, \quad L_{ijkl} \in L^\infty(\Omega).
\]
Generalized solution

Let

\[ f \in L^2(\Omega, \mathbb{R}^n), \quad F \in L^2(\partial_2 \Omega, \mathbb{R}^n). \]

Then, a generalized solution \( u \in V_0 + u_0 \) is defined by the identity

\[
\int_{\Omega} L \varepsilon(u) : \varepsilon(w) \, dx + \langle \ell, w \rangle = 0, \quad \forall w \in V_0, \tag{100}
\]

where

\[
\langle \ell, w \rangle = \int_{\Omega} f \cdot w \, dx + \int_{\partial_2 \Omega} F \cdot w \, ds.
\]
Assume that \( u \) is a smooth function and it satisfies the identity

\[
\int_{\Omega} \mathbb{L} \varepsilon(u) : \varepsilon(w) \, dx + \langle \ell, w \rangle = 0, \quad \forall w \in V_0,
\]

Then,

\[
\int_{\Omega} (f - \text{div}(\mathbb{L} \varepsilon(u)) \cdot w \, dx + \int_{\partial_2 \Omega} \left( (\mathbb{L} \varepsilon(u)) \nu + F \right) \cdot w \, ds = 0,
\]

\[
\forall w \in V_0,
\]

and we observe that in such a case the equilibrium equation and the Neumann boundary condition are satisfied in the classical sense.
Variational formulation

Note that the relation (100) is the Euler’s equation for the functional

\[ J(v) = \frac{1}{2} \int_{\Omega} \mathbb{L}\varepsilon(v) : \varepsilon(v) \, dx + \langle \ell, v \rangle . \]

Therefore, the respective boundary–value problem may be considered as a minimization problem for \( J(v) \) on the set

\[ V_0 := \{ v \in H^1(\Omega, \mathbb{R}^n) \mid v = u_0 \text{ on } \partial_1 \Omega \}. \]

To prove existence of a minimizer we must show the coercivity of \( J(v) \) on \( V_0 \). The key role in this belongs to the so–called Korn’s inequality.
In the Dirichlet problem

\[ J(v) = \frac{1}{2} \int_{\Omega} \mathbb{L} \varepsilon(v) : \varepsilon(v) \, dx + \langle \ell, v \rangle \geq \]

\[ \geq \frac{C_1}{2} \| \varepsilon(v) \|^2 - \| f \| \| v \| = \]

\[ = \frac{C_1}{2} \| \varepsilon(u_0 + w) \|^2 - \| f \| \| u_0 + w \| \geq \]

\[ \geq \frac{C_1}{2} \left( \| \varepsilon(u_0) \| - \| \varepsilon(w) \| \right)^2 - \| f \| \| u_0 \| - \| f \| \| w \|. \]

Thus, if we can prove that

\[ \| \varepsilon(w) \| \geq c \| \nabla w \| \quad \forall w \in H^1(\Omega), \]

then we would establish the coercivity of \( J \).
Korns’s inequality

This inequality is required in various aspects of the mathematical analysis of elasticity problems. In the general form it states the equivalence of two norms:

$$\|w\|_{1,2,\Omega} := \left( \int_{\Omega} (|\nabla w|^2 + |w|^2) \, dx \right)^{1/2},$$

and

$$\|w\|_{1,2,\Omega} := \left( \int_{\Omega} (|\varepsilon(w)|^2 + |w|^2) \, dx \right)^{1/2}.$$
Korn's inequality in $\mathring{H}^1$

For the functions in $\mathring{H}^1(\Omega)$ this fact is not difficult to prove. Indeed, for smooth functions

$$\int_{\Omega} |\varepsilon(w)|^2 dx = \frac{1}{2} \|\nabla w\|^2 + \frac{1}{2} \int_{\Omega} \sum_{ij} w_{i,j} w_{j,i} dx =$$

$$= \frac{1}{2} \|\nabla w\|^2 - \frac{1}{2} \int_{\Omega} \sum_{ij} w_i w_{j,i} dx = \frac{1}{2} \|\nabla w\|^2 + \frac{1}{2} \int_{\Omega} \sum_{ij} w_{i,i} w_{j,j} dx =$$

$$= \frac{1}{2} \|\nabla w\|^2 + \frac{1}{2} \int_{\Omega} \sum_{i} |w_{i,i}|^2 dx.$$

Since smooth functions are dense in $\mathring{H}^1$, we find that

$$\|\nabla w\| \leq \sqrt{2} \|\varepsilon(w)\| \quad \forall w \in \mathring{H}^1(\Omega). \quad (101)$$
By (101) we prove that the energy functional of the elasticity problem for the case of Dirichlet boundary conditions is coercive, i.e.,

$$J(v_k) \to +\infty, \quad \text{as} \quad \|\nabla v_k\| \to +\infty.$$
Rigid deflections

In the analysis of elasticity problems one more notion is often required. It is the so-called *Space of Rigid Deflections* that we denote $\mathbf{RD}(\Omega)$. This space is the kernel of the operator $\varepsilon(w)$, i.e. it contains vector-valued functions $w$ such that

$$\varepsilon(w) = 0.$$ 

It can be defined as follows:

$$\mathbf{RD}(\Omega) := \{ w = w_0 + \omega_0 x \mid w_0 \in \mathbb{R}^n, \omega_0 \in M^{n \times n} \},$$

where $\omega_0(w) = \frac{1}{2}(\nabla w - (\nabla w)^T)$ is a skew-symmetric tensor associated with "rigid rotations".
Implications of the Korn’s inequality

**Theorem**

Let $\Omega$ be a Lipschitz domain and $\partial_1 \Omega$ is a nonempty connected part of the boundary. Then,

$$
\|u\|_{1,p,\Omega} \leq C \left( \int_{\Omega} |\varepsilon(u)|^p \, dx \right)^{\frac{1}{p}} \quad \forall u \in V_0, \quad p \in (1, 2] \tag{102}
$$

**Proof.** Assume the opposite. Then, for any $m \in \mathbb{N}$ we can find $v^{(m)}$ such that $v^{(m)} \in V_0$ and

$$
\|v^{(m)}\|_{1,p,\Omega} > m \left( \int_{\Omega} |\varepsilon(v^{(m)})|^p \, dx \right)^{\frac{1}{p}}.
$$
Set \( w^{(m)} = \frac{v^{(m)}}{\|v^{(m)}\|_{1,p,\Omega}} \), then

\[ \|w^{(m)}\|_{1,p,\Omega} = 1 \quad \text{and} \quad \frac{1}{m} \geq \left( \frac{\int_{\Omega} |\varepsilon(w^{(m)})|^p \, dx}{\int_{\Omega} \varepsilon(w^{(m)}) \, dx} \right)^{\frac{1}{p}}. \]

Therefore,

\[
\begin{align*}
& w^{(m)} \rightharpoonup w \quad \text{in} \quad W_1^1(\Omega, \mathbb{R}^n), \\
& w^{(m)} \to w \quad \text{in} \quad L^p(\Omega, \mathbb{R}^n), \\
& \|\varepsilon(w^{(m)})\|_{p,\Omega} \to 0 \quad \text{in} \quad L^p(\Omega, \mathbb{R}^n).
\end{align*}
\]

From here we conclude that \( \varepsilon(w) = 0 \).
Indeed, by the fact that a norm is weakly lower semicontinuous, we have

$$0 = \liminf_m \| \varepsilon(w^{(m)}) \|_{p,\Omega} \geq \| \varepsilon(w) \|_{p,\Omega}.$$ 

Thus, $w \in RD(\Omega) \cap V$. There is only one such a function: $w = 0$. It means that $w^{(m)} \to 0$ in $L^p$. Now, we apply Korn’s inequality

$$\|w(m)\|_{1,p,\Omega} \leq C \left( \int_\Omega (|\varepsilon(w^{(m)})|^p + |w^{(m)}|^p) \, dx \right)^{\frac{1}{p}} \to 0,$$

which shows that $\|w(m)\|_{1,p,\Omega}$ tends to zero. But for any $m \|w^{(m)}\|_{p,1,\Omega} = 1$, so that such a behavior is impossible. We have arrived at a contradiction that proves the Theorem.
Another similar result is required for the Neumann problem. Define the set

\[
V = \left\{ v \in W^1_p(\Omega) \mid \int_{\Omega} v \cdot w \, dx = 0 \quad \forall w \in RD(\Omega) \right\}.
\]

**Theorem**

*Let \( \Omega \) be a bounded domain with Lipschitz boundary \( \partial \Omega \). Then*

\[
\|u\|_{1,p,\Omega} \leq C \left( \int_{\Omega} |\varepsilon(u)|^p \, dx \right)^{\frac{1}{p}} \quad \forall u \in V.
\] (103)
Proof. By the same arguments as before, we obtain a sequence $w^{(m)} \in V$ such that

$$w^{(m)} \rightharpoonup w \quad \text{in} \quad W^1_p(\Omega, \mathbb{R}^n),$$

$$w^{(m)} \rightarrow w \quad \in \quad L^p(\Omega, \mathbb{R}^n),$$

$$\|\varepsilon(w^{(m)})\|_{p,\Omega} \rightarrow 0 \quad \text{in} \quad L^p(\Omega, \mathbb{R}^n).$$

By the arguments similar to those in the previous Theorem, we find that $\varepsilon(w) = 0$ and, thus, $w \in RD(\Omega)$. In addition, for any $\tilde{w} \in RD$, we have

$$0 = \int_{\Omega} w^{(m)} \cdot \tilde{w} \, dx = \int_{\Omega} w \cdot \tilde{w} \, dx.$$

But $w \in RD$, so that $\|w\| = 0$, and by applying Korn’s inequality we prove that $\|w^{(m)}\|_{1,p,\Omega}$ tends to zero, what leads to a contradiction.
Estimates of deviations

Let $\boldsymbol{v}$ and $\boldsymbol{y}$ be some approximations of $\boldsymbol{u}$ and $\sigma^*$. Estimates of $\boldsymbol{v} - \boldsymbol{u}$ and $\boldsymbol{y} - \sigma^*$ follow from the general scheme if we set

$$
\boldsymbol{U} = L^2(\Omega, \mathbb{M}_s^{n \times n}), \quad \boldsymbol{V} = H^1(\Omega, \mathbb{R}^n),
$$

$$
\mathcal{V}_0 = \{ \boldsymbol{w} \in \mathcal{V} \mid \boldsymbol{w} = 0 \text{ on } \partial_1 \Omega \},
$$

$$
\| \boldsymbol{y} \|^2 = \int_{\Omega} \mathbb{L} \boldsymbol{y} : \boldsymbol{y} \, d\boldsymbol{x}, \quad \| \boldsymbol{y} \|_{*}^2 = \int_{\Omega} \mathbb{L}^{-1} \boldsymbol{y} : \boldsymbol{y} \, d\boldsymbol{x},
$$

and $\Lambda \boldsymbol{v} = \varepsilon(\boldsymbol{v}) := \frac{1}{2} \left( \nabla \boldsymbol{v} + (\nabla \boldsymbol{v})^T \right)$. In this case, $\langle \Lambda^* \boldsymbol{y}, \boldsymbol{w} \rangle = \int_{\Omega} \boldsymbol{y} : \varepsilon(\boldsymbol{w}) \, d\boldsymbol{x}, \quad \forall \boldsymbol{w} \in \mathcal{V}_0,$
Now $y$ is a tensor-valued function and $y_{\nu} = y_{ij}\nu_j$ is a vector–function defined on $\partial \Omega$.

If

$$y \in Q^* := \{ y \in Y^* \mid \text{div}y \in L^2(\Omega, \mathbb{M}^{n\times n}), \ y_{\nu} \in L^2(\partial_2 \Omega, \mathbb{R}^n) \}.$$

then

$$\langle \Lambda^* y, w \rangle = - \int_{\Omega} \text{div} y \cdot w \, dx + \int_{\partial_2 \Omega} (y_{\nu}) \cdot w \, d\Gamma$$

so that

$$\Lambda^* y = \{-\text{div}y \mid \Omega, \ (y_{\nu}) \mid \partial_2 \Omega \}.$$
Upper estimates

By applying the general estimate, we obtain the following upper estimate:

\[
\frac{1}{2} \int_{\Omega} \mathbb{L} \varepsilon(v - u) : \varepsilon(v - u) \, dx \leq \mathbf{M}_\oplus(v, \beta, y),
\]

where

\[
\mathbf{M}_\oplus(v, \beta, y) = \frac{1 + \beta}{2} \mathbf{D}(\varepsilon v, y) + \frac{1 + \beta}{2\beta} \mathbf{I} \mathbf{\Lambda}^* y + \ell \mathbf{I}^2
\]

and

\[
\mathbf{D}(\varepsilon(v), y) = \frac{1}{2} \int_{\Omega} \left( \mathbb{L} \varepsilon(v) : \varepsilon(v) \mathbb{L}^{-1} y : y - 2\varepsilon(v) : y \right) \, dx =
\]

\[
= \int_{\Omega} (\varepsilon(u) - \mathbb{L}^{-1} y) : (\mathbb{L} \varepsilon(u) - y) \, dx.
\]
If \( y \in Q^* \), then

\[
\| \Lambda^* y + \ell \| = \sup_{w \in V_0} \frac{\langle \Lambda^* y + \ell, w \rangle}{\| \Lambda w \|} = \\
= \sup_{w \in V_0} \frac{\int_\Omega (y : \varepsilon(w) + f \cdot w) \, dx + \int_{\partial_2 \Omega} F \cdot w \, ds}{\| \varepsilon(w) \|} = \\
= \sup_{w \in V_0} \frac{\int_\Omega (f - \text{div} y) \cdot w \, dx + \int_{\partial_2 \Omega} (F + y \nu) \cdot w \, ds}{\| \varepsilon(w) \|} \leq \\
\leq \sup_{w \in V_0} \frac{\| f - \text{div} y \|_{2,\Omega} \| w \|_{2,\Omega} + \| F + y \nu \|_{\partial_2 \Omega} \| w \|_{\partial_2 \Omega}}{\| \varepsilon(w) \|}.
\]
Let $C_\Omega$ be a constant in the inequality

$$\int \Omega |w|^2 \, dx + \int_{\partial_2 \Omega} |w|^2 \, ds \leq C_\Omega^2 \|\varepsilon(w)\|^2_\Omega, \quad \forall w \in \mathbf{V}_0.$$ 

Note that the existence of such a constant follows from the Korn’s inequality. Indeed, the inequality

$$\int \Omega |w|^2 \, dx + \int_{\partial_2 \Omega} |w|^2 \, ds \leq \hat{C}_\Omega^2 \|\nabla(w)\|^2_\Omega, \quad \forall w \in \mathbf{V}_0.$$

for the tensor–gradient $\nabla(w)$ follows from the Friederichs type inequality for the vector–valued functions and the respective trace theorems. By (102) we recall that for the functions in $\mathbf{V}_0$

$$\|\nabla(w)\|_\Omega \leq C\|\varepsilon(w)\|_\Omega$$

with a certain constant $C$ and the estimate follows.
In practice, values of $C_\Omega$ can be estimated by minimizing the quotient

$$\frac{\|\epsilon(w)\|_\Omega^2}{\int_\Omega |w|^2 \, dx + \int_{\partial_2 \Omega} |w|^2 \, ds}$$

over sufficiently representative finite dimensional space $V_{0h} \subset V_0$.

Let us now return to finding an upper bound of the quantity $[ \Lambda^* y + \ell ]$. By the inequality $ab + cd \leq \sqrt{a^2 + c^2} \sqrt{b^2 + d^2}$, we obtain

$$[ \Lambda^* y + \ell ] \leq \left( \|\text{div } y - f\|_\Omega^2 + \|F + y\nu\|_{\partial_2 \Omega}^2 \right)^{1/2} \sup_{w \in V_0} \left( \|w\|_\Omega^2 + \|w\|_{\partial_2 \Omega}^2 \right)^{1/2} \||\epsilon(w)||$$

$$\leq C_\Omega c_1^{-1/2} \left( \|\text{div } y - f\|_\Omega^2 + \|F + y\nu\|_{\partial_2 \Omega}^2 \right)^{1/2}$$
Error Majorant for mixed boundary conditions

Hence, we arrive at the Majorant $M_\oplus$:

\[
M_\oplus(\varepsilon(v), y) = \frac{1+\beta}{2} \int_\Omega (\varepsilon(v) - \mathbb{L}^{-1}y) : (\mathbb{L} \varepsilon(v) - y) \, dx + \\
+ \frac{1+\beta}{2\beta c_1} C_\Omega^2 \left( \|\text{div } y - f\|_\Omega^2 + \|F + y\nu\|_{\partial_2 \Omega}^2 \right). \tag{104}
\]

It has a clear physical meaning. The first term of $M_\oplus$ is nonnegative and vanishes if and only if

\[y = \mathbb{L} \varepsilon(v).\]

It penalizes violations of the Hooke’s law. The meaning of the second term is obvious: it contains $L^2$-norms of other two relations, which gives errors in the equilibrium equation and boundary condition for the stress tensor.
Thus, the majorant not only gives an idea of the overall value of the error, but also shows its physically sensible parts.

Let \( \{ Y_k^* \} \subset H^1(\Omega, M^{n\times n}) \) be a collection of finite-dimensional subspaces that satisfy the limit density condition. Then, (104) generates a sequence of computable upper bounds

\[
M_k^\oplus = \inf_{y \in Y_k^*} \inf_{\beta \in \mathbb{R}_+} \left\{ \frac{1+\beta}{2} \int_{\Omega} ( \mathbb{L} \varepsilon(v) : \varepsilon(v) + \mathbb{L}^{-1}y : y - 2\varepsilon(v) : y ) \, dx 
+ \frac{1+\beta}{2\beta c_1} C_\Omega^2 \left( \| \text{div} \, y - f \|^2_\Omega + \| F + y\nu \|^2_{\partial^2 \Omega} \right) \right\},
\]

which tends to the exact value of the error.
Lower estimates also follow from the general theory. We have

\[
\frac{1}{2} \int_{\Omega} \mathbb{L} \varepsilon(v - u) : \varepsilon(v - u) \, dx \geq M_{\Theta}(v, w), \quad \forall w \in V_0,
\]

where

\[
M_{\Theta}(v, w) = -\frac{1}{2} \int_{\Omega} \mathbb{L} \varepsilon(w) : \varepsilon(w) \, dx - \int_{\Omega} \mathbb{L} \varepsilon(v) : \varepsilon(w) \, dx - \int_{\Omega} f \cdot w \, dx - \int_{\partial_2 \Omega} F \cdot w \, ds.
\]

By the same arguments as for the diffusion equation one can prove that

\[
\frac{1}{2} \int_{\Omega} \mathbb{L} \varepsilon(v - u) : \varepsilon(v - u) \, dx = \sup_{w \in V_0} M_{\Theta}(v, w_k).
\]
By the maximization the functional $M_\Theta$ on a sequence of finite-dimensional spaces $V_{0k} \subset V_0$, we obtain a sequence of computable lower bounds

$$M^k_\Theta = \sup_{w \in V_{0k}} M_\Theta(v, w_k).$$

If the spaces $V_{0k}$ satisfy the limit density condition stated, then the sequence of numbers $\{M_\Theta\}$ tends to $\frac{1}{2} \| \varepsilon (v - u) \|^2$. 
Linear elliptic equations of the fourth order

Now, we consider the problem

$$\nabla \cdot \nabla \cdot (B \nabla \nabla u) = f \quad \text{in} \quad \Omega,$$

$$u = \frac{\partial u}{\partial \nu} = 0 \quad \text{on} \quad \partial \Omega.$$  \hspace{1cm} (105)

Here $\Omega \subset \mathbb{R}^2$, $\nu$ denotes the outward unit normal to the boundary, and $B = \{ b_{ijkl} \} \in \mathcal{L}(\mathbb{M}_s^{2 \times 2}, \mathbb{M}_s^{2 \times 2})$. We assume that $b_{ijkl} = b_{jikl} = b_{klij},$

$$\alpha_1 |\eta|^2 \leq B\eta : \eta \leq \alpha_2 |\eta|^2, \quad \forall \eta \in \mathbb{M}_s^{2 \times 2},$$

and

$$f \in L^2(\Omega), \quad b_{ijkl} \in L^\infty(\Omega).$$
To apply the general scheme, we set

\[ U = L^2(\Omega, \mathbb{M}_s^{2 \times 2}), \quad V = H^2(\Omega), \]

\[ V_0 = \{ w \in V \mid w = \frac{\partial w}{\partial \nu} = 0 \text{ on } \partial \Omega \}, \]

and define \( \Lambda \) as the Hessian operator. Now, the basic integral identity has the form

\[
\int_{\Omega} B \nabla \nabla u : \nabla \nabla w \, dx = \int_{\Omega} f w \, dx \quad \forall w \in V_0.
\]  

(107)

By \( B^{-1} \) we denote the inverse tensor, which satisfies the double inequality

\[
\alpha_2^{-1} |\eta|^2 \leq B^{-1} \eta : \eta \leq \alpha_1^{-1} |\eta|^2, \quad \forall \eta \in \mathbb{M}_s^{2 \times 2},
\]
The spaces $Y$ and $Y^*$ are equipped with norms

$$
\| y \|^2 = \int_\Omega B y : y \, dx; \quad \| y \|_{*}^2 = \int_\Omega B^{-1} y : y \, dx,
$$

$$
\langle \ell, w \rangle = -\int_\Omega f w \, dx,
$$

and

$$
Q^*_\ell = \{ y \in Y^* \mid \int_\Omega y : \nabla \nabla w \, dx = \int_\Omega f w \, dx, \quad \forall w \in V_0 \}.
$$

Since

$$
\| \nabla \nabla w \| \geq \alpha_3 \| w \|_{2,2,\Omega} \quad \forall w \in V_0,
$$

we have the required version of the coercivity condition

$$
\| \Lambda w \| \geq c_3 \| w \|_V.
$$

Problem (105) and (106) is associated with two variational problems.
Problem $\mathcal{P}$. Find $u \in V_0$ such that

$$J(u) = \inf_{v \in V_0} J(v),$$

where

$$J(v) = \frac{1}{2} \int_{\Omega} B \nabla \nabla v : \nabla \nabla v \, dx - \int_{\Omega} fw \, dx.$$ 

Problem $\mathcal{P}^\ast$. Find $p \in Q_\ell^\ast$ such that

$$I^\ast(p) = \sup_{\forall \, q \in Q_\ell^\ast} I^\ast(q),$$

where

$$I^\ast(q) = -\frac{1}{2} \int_{\Omega} B^{-1} q : q \, dx.$$
Two basic relations for the deviations that we derived in the previous Lecture now come in the form:

\[ \| \nabla \nabla (v - u) \|^2 + \| q - p \|^2_* = 2(J(v) - l^*(q)) , \quad (108) \]

and

\[ \| \nabla \nabla (v - u) \|^2 + \| q - p \|^2_* = 2D(\nabla \nabla v, q) = \int_{\Omega} \left( B \nabla \nabla v : \nabla \nabla v + B^{-1} q : q - 2 \nabla \nabla v : q \right) \, dx . \quad (109) \]

They hold for any \( v \in V_0 \) and \( q \in Q_*^\ell \).

Also, from the general theory it readily follows the first a posteriori estimate:

\[ \frac{1}{2} \| \nabla \nabla (v - u) \|^2 \leq (1 + \beta)D(\nabla \nabla v, y) + \left( 1 + \frac{1}{\beta} \right) \frac{d_\ell^2(y)}{2} , \quad (110) \]

where \( d_\ell^2(y) = \inf_{q \in Q_*^\ell} \| q - y \|^2_* \).
Note that
\[ \int_{\Omega} y : \nabla \nabla w \, dx = \int_{\Omega} (\text{divdiv } y)w \, dx, \quad \forall w \in V_0, \]
so that \( \Lambda^* : Y^* \rightarrow H^{-2} (\Omega) \) is the operator \( \text{divdiv} \).

Next,
\[ \langle \ell + \Lambda^* y, w \rangle = \int_{\Omega} (y : \nabla \nabla w - fw) \, dx \]
and, therefore,
\[ d^2_\ell (y) = \left[ \ell + \Lambda^* y \right] = \sup_{w \in V_0} \frac{\int_{\Omega} (y : \nabla \nabla w - fw) \, dx}{\| \nabla \nabla w \|}. \]
If
\[ y \in H(\text{divdiv}, \Omega) := \left\{ y \in L^2(\Omega, \mathbb{M}^{n \times n}_s) \mid \text{divdiv} y \in L^2(\Omega) \right\}, \]
then this quantity is estimated by the relation
\[
\left| \ell + \Lambda^* y \right| \leq \sup_{w \in V_0} \frac{\|\text{divdiv} y - f\|_\Omega \|w\|_\Omega}{\|\nabla \nabla w\|} \leq \sup_{w \in V_0} \frac{\|\text{divdiv} y - f\|_\Omega \|w\|_\Omega}{\alpha_1 \|\nabla \nabla w\|} \leq \frac{C_{1\Omega}}{\alpha_1} \|\text{divdiv} y - f\|_\Omega,
\]
in which \( C_{1\Omega} \) is a constant in the inequality
\[
\|w\|_\Omega \leq C_{1\Omega} \|\nabla \nabla w\|_\Omega \quad \forall w \in V_0.
\]

Now, we obtain the first variant of a posteriori estimate for the biharmonic type problem.
First a posteriori estimate

\[
\frac{1}{2} \| \nabla \nabla (v - u) \|^2 \leq (1 + \beta)D(\nabla \nabla v, y) + \\
+ \left(1 + \frac{1}{\beta}\right) \frac{C_{1\Omega}^2}{2\alpha_1^2} \| \text{div div } y - f \|_{\Omega}^2, \tag{111}
\]

Here, \( y \) is an arbitrary tensor-valued function from \( \mathbb{H} (\text{div div}, \Omega) \) and \( \beta \) is a positive real number. However, this is rather demanding in relation to the dual variable \( y \) (which must have square summable \( \text{div div} \)). To avoid technical difficulties that rises from this condition, we estimate the negative norm in a different way.
\[ \ell + \Lambda^* y = \sup_{w \in V_0} \frac{\int (y : \nabla \nabla w - f w) \, dx}{\| \nabla \nabla w \|} = \sup_{w \in V_0} \frac{\int (y : \nabla \nabla w + \eta \cdot \nabla w + \text{div} \eta w - f w) \, dx}{\| \nabla \nabla w \|} = \sup_{w \in V_0} \frac{\int (-\text{div} y \cdot \nabla w + \eta \cdot \nabla w + \text{div} \eta w - f w) \, dx}{\| \nabla \nabla w \|} \leq \frac{C_{2\Omega}}{\alpha_1} \| \text{div} y - \eta \|_\Omega + \frac{C_{1\Omega}}{\alpha_1} \| \text{div} \eta - f \|_\Omega. \]

Here, \( \eta \) is an arbitrary vector-valued function from \( H(\text{div}, \Omega) \) and \( C_{2\Omega} \) is a constant in the inequality

\[ \| \nabla w \|_\Omega \leq C_{2\Omega} \| \nabla \nabla w \|_\Omega \quad \forall w \in V_0. \]
Second a posteriori estimate

Then, we arrive at the estimate

\[
\frac{1}{2} \| \nabla \nabla (v - u) \|^2 \leq (1 + \beta) \mathcal{D}(\nabla \nabla v, y) +
+ \left(1 + \frac{1}{\beta}\right) \frac{1}{2\alpha_1^2} (C_2 \| \text{div} y - \eta \| \Omega + C_1 \| \text{div} \eta - f \| \Omega)^2,
\]

in which \( y \in \Sigma_{\text{div}}(\Omega) \) and \( \eta \in H(\text{div}, \Omega) \).

This estimate was obtained in
P. Neittaanmäki and S. Repin. A posteriori error estimates for boundary-value problems related to the biharmonic operator,
Note that

\[ \|w\| \leq C_F \|\nabla w\|_\Omega \leq C_F C_{2\Omega} \|\nabla \nabla w\|_\Omega \quad \forall w \in V_0. \]

where \(C_F\) is a constant in the Friederichs inequality. Therefore,
\(C_{1\Omega} \leq C_F C_{2\Omega}\). In view of this, we obtain a slightly different form of the deviation estimate:

\[ \frac{1}{2} \|\nabla \nabla (v - u)\|^2 \leq (1 + \beta) D(\nabla \nabla v, y) + \left(1 + \frac{1}{\beta}\right) \frac{C_{2\Omega}^2}{2\alpha_1^2} (\|\text{div} y - \eta\|_\Omega + C_F \|\text{div} \eta - f\|_\Omega)^2, \quad (113) \]

For boundary conditions of other types, the deviation majorants can be derived by arguments similar to those used in Lecture 6.
Lower estimates of the deviation from $u$

Lower estimates follow from the general estimate discussed in Lecture 5. We have

$$\frac{1}{2} \| \nabla \nabla (v - w) \|^2 \geq M_\Theta (v, w) \quad w \in V_0,$$

where

$$M_\Theta (v, w) := -\frac{1}{2} \| \nabla \nabla w \|^2 - \int_\Omega (B \nabla \nabla v : \nabla \nabla w - fw) dx.$$
A POSTERIORI ESTIMATES IN NON-ENERGY QUANTITIES
If we can estimate the energy error norm, then we can estimate all other quantities subject to it.
General Principle

If

\[ \| u - v \| \leq M^\oplus \]

and

\[ \phi(u - v) \leq C \| u - u_a \| \]

then

\[ \phi(u - v) \leq CM^\oplus \]
Example

By the embedding theorems we know that for any Lipschitz domain

If \( q \geq 1 \), and \( 1 + \frac{n}{q} \geq \frac{n}{2} \), then \( W^{1,2}(\Omega) \) is continuously embedded in \( L^q(\Omega) \), i.e.,

\[
\|w\|_{q,\Omega} \leq C(\Omega, q)\|w\|_{1,2,\Omega}
\]

If \( 1 > \frac{n}{2} \), then \( W^{1,2}(\Omega) \) is compactly embedded in \( C(\Omega) \), i.e.,

\[
\|w\|_{C(\Omega)} \leq \hat{C}(\Omega)\|w\|_{1,2,\Omega}
\]
If the conditions of above theorems hold, then we obtain

\[ \| u - v \|_{q, \Omega} \leq C(\Omega, q) M_\oplus(v, y) \]

Note that if \( n = 2 \) then the above relation holds for any finite \( q \).

\[ \text{esssup}_{x \in \Omega} \| u(x) - v(x) \| \leq C(\Omega, q) M_\oplus(v, y) \]
ERROR ESTIMATES IN TERMS OF GOAL-ORIENTED FUNCTIONALS

\[ \ell(u - v) \leq M_{\ell^{\oplus}} \]

Example:

\[ < \ell, u - v > = \int_{\Omega} \varphi(u - v) \, dx, \]

where the weight \( \varphi \) is a locally supported function.
Let us consider the methods of goal-oriented error control on the paradigm of our Basic Linear Problem.

\[(A\Lambda u, \Lambda w) = \langle f, w \rangle, \quad \forall w \in V_0.\]  

(115)

\[A \in \mathcal{L}(U, U),\]
\[\Lambda \in \mathcal{L}(V, U),\]
\[V\text{ is a Banach space}, \quad V_0\text{ is a subspace of } V, \quad f \in V_0^*,\]
\[U\text{ is a Hilbert space equipped with scalar product } (\cdot, \cdot),\]
\[\langle \cdot, \cdot \rangle\text{ denotes the duality pairing of } V_0 \text{ and } V_0^*.\]
We assume that the operators $\mathcal{A}$ and $\Lambda$ satisfy the conditions

\begin{align*}
    c_1 \|y\|_U^2 &\leq (\mathcal{A}y, y) \leq c_2 \|y\|_U^2, \quad \forall y \in U, \quad (116) \\
    c_3 \|w\|_V &\leq \|\Lambda w\|_U, \quad \forall w \in V_0, \quad (117)
\end{align*}

Our aim is to derive estimates of the quantity

\[ < \ell, u - v >, \]

where $v$ is an arbitrary element from $V_0$. 

It consists of the attraction the **adjoint problem**.
Adjoint problem

Find $u_a \in V_0$ such that

$$ (A^* w, w) = \langle \ell, w \rangle \quad \forall w \in V_0, $$

(118)

where $A^*$ is the operator adjoint to $A$, i.e.,

$$ (Ay, z) = (y, A^* z) \quad \forall y, z \in U. $$
Proposition

Let \( u, v \) and \( u_a, v_a \) be exact and approximate solutions of the primal and adjoint problems respectively. Then,

\[
\langle \ell, u - v \rangle := E(v, v_a) = E_0(v, v_a) + E_1(v, v_a),
\]

(119)

where

\[
E_0(v, v_a) = \langle f, v_a \rangle - (A\Lambda v, \Lambda v_a)
\]

(120)

and

\[
E_1(v, v_a) = (A\Lambda (u - v), \Lambda (u_a - v_a)).
\]

(121)
Proof.

Since \( u_a \) is a solution of the adjoint problem, we have

\[
< \ell, u - v > = (A^* \Lambda u_a, \Lambda (u - v)) =
= (A \Lambda (u - v), \Lambda u_a) =
= (A \Lambda (u - v), \Lambda (u_a - v_a)) + < f, v_a > - (A \Lambda v, \Lambda v_a).
\]
\( E_0(v, v_a) \) is explicitly computable!
\( E_1(v, v_a) \) contains unknown solutions of the two problems.
Let \( V_h \) and \( V_\tau \) be two finite-dimensional subspaces of \( V_0 \), and let \( v = u_h \) and \( v_a = u_a\tau \), where \( u_h \) and \( u_a\tau \) are solutions of the problems

\[
(\mathcal{A}\Lambda u_h, \Lambda w_h) = < f, w_h > \quad \forall w_h \in V_h, \quad (122)
\]

\[
(\mathcal{A}^*\Lambda u_a\tau, \Lambda w_\tau) = < \ell, w_\tau > \quad \forall w_\tau \in V_\tau. \quad (123)
\]
In the particular case $\mathbf{V}_h \equiv \mathbf{V}_\tau$, the relation (122) implies that $E_0(u_h, u_{a\tau}) = 0$ so that there remains the term containing the product of the (unknown) energy errors. On the contrary, for noncoinciding spaces both terms $E_0$ and $E_1$ are present. Moreover, it is easy to show that the term $E_0$ dominates if $v_a$ is close to $u_a$. Indeed, if $v_a \rightarrow u_a$ in $\mathbf{V}$, then $\Lambda(u_a - v_a) \rightarrow 0$ in $\mathbf{U}$, so that

$$E_1(v, v_a) \rightarrow 0.$$ 

However,

$$E_0(v, v_a) + E_1(v, v_a) = \langle \ell, u - v \rangle \neq 0.$$ 

Hence, if $v_a$ is sufficiently close to $u_a$, then the directly computable term $E_0(v, v_a)$ contains the major part of the estimated quantity.
Key question: how to estimate

$$E_1(v, v_a) = (A\Lambda(u - v), \Lambda(u_a - v_a)).$$

Two ways.

- Economical method that gives correct presentation on the error but does not give guaranteed error bounds,
- Computationally expensive method that provides two–sided guaranteed error bounds for the goal–oriented functional.
Economical way: use post-processing methods

Main idea: recover the unknown functions $\Lambda u$ and $\Lambda u_a$ by some post-processing techniques.

See: S. Korotov, P. Neittaanmaki and S. Repin, 
Let $G_h$ and $G_\tau$ be averaging operators defined on $V_h$ and $V_\tau$, respectively. Replace $E(u_h, u_{a\tau})$ by the directly computable functional

$$
\tilde{E}(u_h, u_{a\tau}) := E_0(u_h, u_{a\tau}) + \tilde{E}_1(u_h, u_{a\tau}),
$$

(124)

where

$$
\tilde{E}_1(u_h, u_{a\tau}) = (A(G_h(\Lambda u_h) - \Lambda u_h), G_\tau(\Lambda u_{a\tau}) - \Lambda u_{a\tau}).
$$

If the operators $G_h$ and $G_\tau$ perform a proper recovery of $\Lambda u_h$ and $\Lambda u_{a\tau}$, then it is natural to expect that the difference between $E_1(u_h, u_{a\tau})$ and $\tilde{E}(u_h, u_{a\tau})$ is given by higher order terms and, thus, the latter quantity can successfully be used instead of $E_1$. 
Two–sided estimates

Main idea: is to apply two-sided error estimates given by $M_\oplus$ and $M_\ominus$ to derive sharp bounds of $\langle A\Lambda(u - v), \Lambda(u_a - v_a) \rangle$ using a special representation of this term.

Certainly, we may simply use the estimate

\[ (A \Lambda(u - v), \Lambda(u_a - v_a)) \leq \| \Lambda(u - v) \| \| \Lambda(u_a - v_a) \|. \]

However, it may considerably **overestimate** the error. Therefore, it is suggested to use the algebraic relation

\[ 2ab = \left( \alpha a + \frac{1}{\alpha} b \right)^2 - \alpha^2 a^2 - \frac{1}{\alpha^2} b^2. \]
We have

\[ \langle \ell, u - v \rangle := E(v, v_a) = E_0(v, v_a) + E_1(v, v_a), \]  

(125)

where \( v \) is an approximation of \( u \), \( v_a \) is an approximation of \( u_a \), and

\[
E_0(v, v_a) = \langle f, v_a \rangle - (A\Lambda v, \Lambda v_a),
\]

\[
E_1(v, v_a) = (A\Lambda \delta_f, \Lambda \delta_\ell), \quad \delta_f = (u - v), \quad \delta_\ell = (u_a - v_a).
\]

By the algebraic identity

\[
2(A\Lambda \delta_\ell, \Lambda \delta_f) =
\]

\[
= \| \Lambda (\alpha \delta_f + \frac{1}{\alpha} \delta_\ell) \|^2 - \alpha^2 \| \Lambda \delta_f \|^2 - \frac{1}{\alpha^2} \| \Lambda \delta_\ell \|^2. \quad (126)
\]
Assume that for the primal and adjoint problems we have found good upper and lower error bounds in the energy norm, i.e., we have $y_f^*$, $y_\ell^*$, $\beta_f$, $\beta_\ell$, $w_f$, and $w_\ell$ such that

$$m_f := M_\ominus(v, w_f) \leq \frac{1}{2} \| \Lambda \delta_f \|^2 \leq M_\oplus(v, \beta_f, y_f^*) := M_f,$$

$$m_\ell := M_\ominus(v_a, w_\ell) \leq \frac{1}{2} \| \Lambda \delta_\ell \|^2 \leq M_\oplus(v_a, \beta_\ell, y_\ell^*) := M_\ell.$$
Note that the quantity
\[
\|\Lambda(\alpha \delta_f + \frac{1}{\alpha} \delta_\ell)\|^2 = \|\Lambda(\alpha u + \frac{1}{\alpha} u_a - \alpha v - \frac{1}{\alpha} v_a)\|^2
\]
can be viewed as the norm of the difference between the exact solution
\(u_{f\ell}^\alpha \in V_0 + (\alpha + \frac{1}{\alpha})u_0\) of the problem
\[
(\mathcal{A}\Lambda u_{f\ell}^\alpha, \Lambda w) + \langle \alpha f + \frac{1}{\alpha} \ell, w \rangle = 0, \quad \forall w \in V_0
\]
and the function \(v_{a f\ell}^\alpha = \alpha v + \frac{1}{\alpha} v_a \in V_0 + (\alpha + \frac{1}{\alpha})u_0\), which is an approximation of \(u_{f\ell}^\alpha\).
To obtain two-sided bounds of \( \| \Lambda(\alpha \delta_f + \frac{1}{\alpha} \delta_\ell) \|^2 \) we use already known functions \( y_f^*, y_\ell^* \), \( w_f \), and \( w_\ell \) and compute the numbers

\[
m_{f\ell} = \mathcal{M}_\oplus(u_{a_{f\ell}}^\alpha, \alpha w_f + \frac{1}{\alpha} w_\ell),
\]

\[
M_{f\ell} = \mathcal{M}_\ominus(u_{a_{f\ell}}^\alpha, \beta, \alpha y_f^* + \frac{1}{\alpha} y_\ell^*).
\]

We note that \( m_{f\ell} = m_{f\ell}(\alpha) \), \( M_{f\ell} = M_{f\ell}(\alpha, \beta) \) and positive numbers \( \alpha \) and \( \beta \) can be taken arbitrary. By (126), we obtain

\[
(\mathcal{A}\Lambda \delta_f, \Lambda \delta_\ell) \leq \inf_{\alpha, \beta \in \mathbb{R}_+} \left\{ M_{f\ell} - \alpha^2 m_f - \frac{m_\ell}{\alpha^2} \right\} := \mathcal{M}_\oplus,
\]

\[
(\mathcal{A}\Lambda \delta_f, \Lambda \delta_\ell) \geq \sup_{\alpha \in \mathbb{R}_+} \left\{ m_{f\ell} - \alpha^2 M_f - \frac{M_\ell}{\alpha^2} \right\} := \mathcal{M}_\ominus.
\]
Recalling (125), we now deduce a two-sided estimate

\[ M_\oplus + E_0(v, v_a) \leq \langle \ell, u - v \rangle \leq M_\ominus + E_0(v, v_a), \quad (127) \]

If \( y_f^*, y_\ell^*, w_f, \) and \( w_\ell \) provide accurate two-sided estimates of the energy error norms in the primal and adjoint problems, then \( M_{f, \ell} \) and \( m_{f, \ell} \) furnish accurate two-sided estimates for the norm \( \| \Lambda(\alpha \delta_f + \frac{1}{\alpha} \delta_\ell) \|^2 \) and, consequently, (127) yields sharp upper and lower bounds of \( \langle \ell, u - v \rangle \).
Error estimates in terms of seminorms

Estimates of \( u - v \) computed on a set of linear functionals can be used for an evaluation of this difference in some seminorms. Let \( \omega \) be a subdomain in \( \Omega \) and \( \{ \varphi_1, \varphi_2, ..., \varphi_d \} \) be a set of functions that vanish in \( \Omega \setminus \omega \). By the method described above, we can estimate the quantities

\[
I_{\varphi_s} := \int_{\omega} \varphi_s(x)(u(x) - v(x)) \, dx.
\]

Using these quantities we can estimate the error in terms of local seminorms.
Let
\[ \|u - v\|_{2,\omega}^2 := \int_\omega |u(x) - v(x)|^2 \, dx. \]

Note that
\[ \|u - v\|_{2,\omega} = \sup_{\eta \in L^2(\omega)} \frac{\int_\omega \eta(u - v) \, dx}{\|\eta\|_{2,\omega}}, \]

and the supremum is attained if \( \eta = u - v \).
Thus, if the difference $\mathbf{u} - \mathbf{v}$ is known to belong to a certain set $\mathfrak{N}(\omega) \subset L^2(\omega)$, then the problem is reduced to the evaluation of the seminorm

$$|\mathbf{u} - \mathbf{v}|_{\mathfrak{N}} := \sup_{\eta \in \mathfrak{N}(\omega)} \int_{\omega} \eta (\mathbf{u} - \mathbf{v}) \, dx \|\eta\|_{2,\omega}.$$

In general, a seminorm does not provide complete information on the error, because the relation $|\mathbf{u} - \mathbf{v}|_{\mathfrak{N}} = 0$ does not mean that $\mathbf{u} = \mathbf{v}$. Nevertheless, seminorms may give a useful information if $\mathfrak{N}$ contains sufficiently large amount of linearly independent functions.
Let $\Upsilon$ be a subspace made by $\varphi_s$, i.e.,

$$
\Upsilon = \text{Span} \{ \varphi_1, \varphi_2, \ldots, \varphi_d \} = \left\{ \sum_s \alpha_s \varphi_s \right\}.
$$

Then,

$$
|u - v|_{\Upsilon} = \sup_{a_i \in \mathbb{R}} \left( \sum_{i=1}^{d} a_i \int_{\omega} \varphi_i (u - v) dx \right) \left( \sum_{i,j=1}^{d} a_i a_j \int_{\omega} \varphi_i \varphi_j dx \right)^{\frac{1}{2}}.
$$

(128)

This problem is equivalent to the following one:
\[
\inf_{a_i \in \mathbb{R}} \sum_{i,j=1}^{d} a_i a_j \int_{\omega} \varphi_i \varphi_j \, dx.
\]

for all \(a_i\) such that

\[
\sum_{i=1}^{d} a_i \int_{\omega} \varphi_i (u - v) \, dx = 1
\]

The latter problem can be reformulated as:
Problem. Find the quantity

$$\kappa^2(\omega, \Upsilon) = \inf_{a \in Q} B a \cdot a,$$

(129)

where $a = (a_1, a_2, \ldots, a_d)$,

$$Q = \{a \in \mathbb{R}^d | a \cdot l = 1\}, \quad l = (l_{\phi_1}, l_{\phi_2}, \ldots, l_{\phi_d}),$$

and

$$B = \{b_{ij}\}_{i,j=1,d}, \quad b_{ij} = \int_{\omega} \phi_i \phi_j \, dx.$$
The problem \((129)\) has a minimax form

\[
\kappa^2(\omega, \Upsilon) = \inf_{a \in \mathbb{R}^d} \sup_{\lambda \in \mathbb{R}} \left\{ B \, a \cdot a + \lambda [(a \cdot I) - 1] \right\} \geq
\]

\[
\geq \sup_{\lambda \in \mathbb{R}} \inf_{a \in \mathbb{R}^d} \left\{ B \, a \cdot a + \lambda [(a \cdot I) - 1] \right\}.
\]

(130)

Assume that the functions \(\varphi_i\) are chosen in such a way that \(B\) is a positive definite matrix. Then \((130)\) holds as equality. The minimization problem that stands on the right-hand side in \((130)\) has a solution

\[
a = -\frac{\lambda}{2} B^{-1} I.
\]
Therefore,
\[
\kappa^2(\omega, \Upsilon) = \sup_{\lambda \in \mathbb{R}} \left\{ -\frac{\lambda^2}{4} B^{-1} \mathbf{l} \cdot \mathbf{l} - \lambda \right\} = \frac{1}{B^{-1} \mathbf{l} \cdot \mathbf{l}},
\]
and
\[
|u - v|_{\Upsilon}^\Upsilon = \frac{1}{\kappa(\omega, \Upsilon)} = (B^{-1} \mathbf{l} \cdot \mathbf{l})^{\frac{1}{2}}.
\]
We see that the value of \(|u - v|_{\Upsilon}^\Upsilon\) is not difficult to find, provided that the functions \(\{\varphi_s\}\) are properly chosen and the respective quantities \(l_{\varphi_s}\) are defined.
Let us show that if \( \mathbf{v} \in \Upsilon(\omega) \) and \( \mathbf{u} \) is a sufficiently smooth function, then the seminorm \( |u - v|_{\Upsilon} \) gives a good estimate of \( \|u - v\|_{2,\omega} \). Let \( \Upsilon(\omega) \) be a subspace of \( L^2(\omega) \) and \( \hat{u} \) be an arbitrary function from \( \Upsilon(\omega) \). Then

\[
\|u - v\|_{2,\omega} = \sup_{\eta \in L^2(\omega)} \frac{\int_{\omega} ((u - \hat{u})\eta + (\hat{u} - v)\eta) \, dx}{\|\eta\|_{2,\omega}} \leq \sup_{\eta \in L^2(\omega)} \frac{\int_{\omega} (\hat{u} - v)\eta \, dx}{\|\eta\|_{2,\omega}} \leq \sup_{\eta \in L^2(\omega)} \frac{\int_{\omega} (\hat{u} - v)\eta \, dx}{\|\eta\|_{2,\omega}} + \|u - \hat{u}\|_{2,\omega}.
\]
Since $\hat{u} - v \in \Upsilon(\omega)$, we have

$$\|u - v\|_{2,\omega} \leq \sup_{\eta \in \Upsilon(\omega)} \frac{\int (\hat{u} - v) \eta \, dx}{\|\eta\|_{2,\omega}} + \|u - \hat{u}\|_{2,\omega}.$$

By rearranging again the numerator of the fraction on the right-hand side, we arrive at the estimate

$$\|u - v\|_{2,\omega} = \sup_{\eta \in \Upsilon(\omega)} \frac{\int (\hat{u} - u) \eta + (u - v) \eta \, dx}{\|\eta\|_{2,\omega}} + \|u - \hat{u}\|_{2,\omega} \leq \int (u - v) \eta \, dx \leq \sup_{\eta \in \Upsilon(\omega)} \frac{\int (u - v) \eta \, dx}{\|\eta\|_{2,\omega}} + 2\|u - \hat{u}\|_{2,\omega} = |u - v|_{\Upsilon} + 2\|u - \hat{u}\|_{2,\omega},$$

in which $\hat{u}$ is an arbitrary function from $\Upsilon(\omega)$. 
Hence, we see that
\[ \|u - v\|_{2,\omega} \leq |u - v|_T + 2\text{dist}(u, \gamma(\omega)), \]
where
\[ \text{dist}(u, \gamma(\omega)) = \inf_{\hat{u} \in \gamma(\omega)} \|u - \hat{u}\|_{2,\omega} \]
is the distance between \(u\) and \(\gamma(\omega)\).
If \(\gamma(\Omega)\) is a set of polynomials and \(u\) is a smooth function then \(\delta(u, \gamma(\omega))\) can be estimated with the help of well-known results of approximation theory.
By similar arguments, we obtain

\[ \|u - v\|_{2, \omega} = \sup_{\eta \in L^2(\omega)} \frac{\int ((u - \hat{u})\eta + (\hat{u} - v)\eta) \, dx}{\|\eta\|_{2, \omega}} \geq \sup_{\eta \in L^2(\omega)} \frac{\int (\hat{u} - v) \eta \, dx}{\|\eta\|_{2, \omega}} - \|u - \hat{u}\|_{2, \omega}. \]

Since \( \hat{u} - v \) belongs to \( \Upsilon(\omega) \), we can replace in the first integral \( \eta \in L^2 \) by \( \eta \in \Upsilon \).

Then, we obtain
\[ \|u - v\|_{2,\omega} \geq \sup_{\eta \in \mathcal{Y}(\omega)} \frac{\int ((\hat{u} - u)\eta + (u - v)\eta) \, dx}{\|\eta\|_{2,\omega}} - \|u - \hat{u}\|_{2,\omega} \geq \sup_{\eta \in \mathcal{Y}(\omega)} \frac{\int (u - v)\eta \, dx}{\|\eta\|_{2,\omega}} - \sup_{\eta \in L^2(\omega)} \frac{\int (\hat{u} - u)\eta \, dx}{\|\eta\|_{2,\omega}} - \|u - \hat{u}\|_{2,\omega} = |u - v|_{\mathcal{Y}} - 2\|u - \hat{u}\|_{2,\omega}, \quad \forall \hat{u} \in \mathcal{Y}(\omega). \]

From here, it follows that

\[ \|u - v\|_{2,\omega} \geq |u - v|_{\mathcal{Y}} - 2\text{dist}(u, \mathcal{Y}(\omega)). \quad (132) \]

By (131) and (132), we conclude that the error arising if \(\|u - u_h\|_{2,\Omega}\) is replaced by \(|u - u_h|_{\mathcal{Y}}\) depends on the regularity of \(u\) and approximation properties of \(\mathcal{Y}(\omega)\).
Lecture 6

A POSTERIORI ESTIMATES FOR MIXED METHODS
Mixed approximations. A glance from the minimax theory

Consider our basic problem

\[ \text{div} A \nabla u + f = 0 \quad \text{in} \quad \Omega, \]
\[ u = u_0 \text{ on } \partial_1 \Omega, \]
\[ A \nabla u \cdot n = F \text{ on } \partial_2 \Omega, \]

\[ c_1^2 |\xi|^2 \leq A(x) \xi \cdot \xi \leq c_2^2 |\xi|^2 \quad \forall \xi \in \mathbb{R}^d, \text{ for a.e. } x \in \Omega, \]

where \( u_0 \in H^1(\Omega) \), \( f \in L^2(\Omega) \), \( F \in L^2(\partial_2 \Omega) \). Functional spaces

\[ V := H^1(\Omega), \quad V_0 := \{ v \in V \mid v = 0 \text{ on } \partial_1 \Omega \}, \quad \hat{V} := L^2(\Omega), \]
\[ Q := L^2(\Omega; \mathbb{R}^d) \]
\[ \hat{Q} := H(\Omega; \text{div}) \]
\[ \hat{Q}^+ := \{ y \in \hat{Q} \mid y \cdot n|_{\partial_2 \Omega} \in L^2(\partial_2 \Omega) \}. \]
We recall that $\|q\|_{\text{div}}$ is the norm in $H(\Omega; \text{div})$:

$$\|q\|_{\text{div}} := (\|q\|^2 + \|\text{div}q\|^2)^{1/2} \quad \forall q \in Q$$

and

$$\|q\| := \left( \int_{\Omega} Aq \cdot q \, dx \right)^{1/2}, \quad q \in Q$$

$$\|q\|_* := \left( \int_{\Omega} A^{-1}q \cdot q \, dx \right)^{1/2}$$

Note that,

$$\bar{c}_1^2|\xi|^2 \leq A^{-1}(x)\xi \cdot \xi \leq \bar{c}_2^2|\xi|^2 \quad \forall \xi \in \mathbb{R}^d, \text{ for a.e. } x \in \Omega$$

with $\bar{c}_1 = 1/c_2$, $\bar{c}_2 = 1/c_1$. 
Generalized solution can be viewed as a saddle point of the Lagrangian

$$L(v, q) := \int_{\Omega} \left( \nabla v \cdot q - \frac{1}{2} A^{-1} q \cdot q \right) dx - \ell(v),$$

where $$\ell(v) = \int_{\Omega} f v dx + \int_{\partial_2 \Omega} F v ds.$$ 

The problem of finding $$(u, p) \in V_0 + u_0 \times Q$$ such that

$$L(u, q) \leq L(u, p) \leq L(v, p) \quad \forall q \in Q, \quad \forall v \in V_0 + u_0$$

leads to is the so-called Primal Mixed Formulation
In this formulation the **solution** of a PDE is understood as the **pair of functions** \((u, p) \in (V_0 + u_0) \times Q\) satisfying the relations

\[
\int_{\Omega} \left( A^{-1} p - \nabla u \right) \cdot q \, dx = 0 \quad \forall q \in Q, \tag{134}
\]

\[
\int_{\Omega} p \cdot \nabla w \, dx - \ell(w) = 0 \quad \forall w \in V_0. \tag{135}
\]

In the PMM,

\[p = A \nabla u,\]  
is satisfied in \(L_2(\Omega)\) – sense  
\[\text{div} p + f = 0 \text{ in } \Omega \text{ and } p \cdot n = F \text{ on } \partial_2 \Omega\] are satisfied in a weak sense.
As we have seen in previous lectures $L$ generates two functionals

$$J(v) := \sup_{q \in Q} L(v, q) = \frac{1}{2} \| \nabla v \|^2 - \ell(v)$$

and

$$I^*(q) := -\frac{1}{2} \| q \|^2_* - \ell(u_0) + \int_\Omega \nabla u_0 \cdot q \, dx .$$

Also, we know that

$$\inf_{v \in V_0 + u_0} J(v) := \inf P = L(u, p) = \sup P^* := \sup_{q \in Q_\ell} I^*(q) , \quad (136)$$

where $Q_\ell := \{ q \in Q \mid \int_\Omega q \cdot \nabla w \, dx = \ell(w) \; \forall w \in V_0 \}$. 
Primal Mixed Method (PMM)

Let $Q_h \subset Q$ and $V_{0h} \subset V_0$ are subspaces constructed by FE approximation, then a discrete analog of (134)–(135) is the **Primal Mixed Finite Element Method**.

In PMM, we need to find a pair of functions 
\((u_h, p_h) \in (V_{0h} + u_0) \times Q_h\) such that

\[
\int_{\Omega} (A^{-1}p_h - \nabla u_h) \cdot q_h \, dx = 0 \quad \forall q_h \in Q_h, \tag{137}
\]

\[
\int_{\Omega} p_h \cdot \nabla w_h \, dx - \ell(w_h) = 0 \quad \forall w_h \in V_{0h}. \tag{138}
\]

In this formulation, \(u_h\) can be constructed by means of the Courant-type elements and \(p_h\) by piecewise constant functions.
Dual Mixed Method (DMM)

Another mixed formulation arises if we represent \( L \) in a somewhat different form. First, we introduce the functional \( g : (V_0 + u_0) \times \hat{Q} \rightarrow \mathbb{R} \) by the relation

\[
g(v, q) := \int_{\Omega} (\nabla v \cdot q + v(\text{div} q)) \, dx.
\]

We have

\[
L(v, q) = \int_{\Omega} \left( \nabla v \cdot q - \frac{1}{2} A^{-1} q \cdot q \right) \, dx - \ell(v) =
\]

\[
= g(v, q) - \int_{\Omega} v(\text{div} q) \, dx - \frac{1}{2} \| q \|_*^2 - \ell(v).
\]
Introduce the set

$$\hat{Q}_F := \{ q \in \hat{Q} \mid g(w, q) = \int_{\partial_2 \Omega} Fw \, ds \quad \forall w \in V_0 \}.$$ 

Note that for $q \in \hat{Q}_F$ we have

$$g(v, q) = g(w + u_0, q) = g(w, q) + g(u_0, q) =$$

$$= \int_{\partial_2 \Omega} Fw \, ds + g(u_0, q) \quad \forall w \in V_0.$$

Therefore, if the variable $q$ is taken not from $Q$ but from the narrower set $\hat{Q}_F$, then the Lagrangian can be written as

$$\hat{L}(v, q) :=$$

$$-\frac{1}{2} \| q \|_*^2 - \int_{\Omega} v(\text{div}q) \, dx - \int_{\Omega} fv \, dx - \int_{\partial_2 \Omega} Fu_0 \, ds + g(u_0, q).$$
We observe that the new Lagrangian \( \hat{L} \) is defined on a wider set of primal functions \( v \in \hat{V} \), but uses a narrower set \( \hat{Q}_F \) for the fluxes.

The problem of finding \( (\hat{u}, \hat{p}) \in \hat{V} \times \hat{Q}_F \) such that

\[
\hat{L}(\hat{u}, q) \leq \hat{L}(\hat{u}, \hat{p}) \leq \hat{L}(\hat{v}, \hat{p}) \quad \forall q \in \hat{Q}_F, \forall \hat{v} \in \hat{V}
\]

lead to is the so-called

**Dual Mixed Formulation**

of the problem in question (see, e.g., F. Brezzi and M. Fortin).
From (139) we obtain the necessary conditions for the dual mixed formulation. Since

$$\hat{L}(\hat{u}, \hat{q}) \leq \hat{L}(\hat{u}, \hat{p}) \quad \forall \hat{q} \in \hat{Q}_F,$$

we have

$$-\frac{1}{2} \| \hat{p} + \lambda \eta \|_{\ast}^2 - \int_{\Omega} \hat{u}(\text{div}(\hat{p} + \lambda \eta) - \hat{f}\hat{u})\,dx - \int_{\partial_2 \Omega} \hat{F}_0 \, ds + g(u_0, \hat{p} + \lambda \eta) \leq$$

$$-\frac{1}{2} \| \hat{p} \|_{\ast}^2 - \int_{\Omega} \hat{u}(\text{div}\hat{p}) \, dx - \int_{\Omega} \hat{f}\hat{u} \, dx - \int_{\partial_2 \Omega} \hat{F}_0 \, ds + g(u_0, \hat{p}),$$

where $\lambda$ is a real number and $\eta$ is a function in $\hat{Q}_0 := \hat{Q}_F$ with $F = 0$. Now, arrive at the relation

$$-\lambda \int_{\Omega} (A^{-1}\hat{p} \cdot \eta + \hat{u}(\text{div}\eta))\,dx + \lambda g(u_0, \eta) \leq \frac{\lambda^2}{2} \int_{\Omega} A^{-1}\eta \cdot \eta\,dx.$$
Rewrite it as

\[ \int_{\Omega} (A^{-1}\hat{p} \cdot \eta + \hat{u}(\text{div} \eta))dx - g(u_0, \eta) \geq \frac{\lambda}{2} \int_{\Omega} A^{-1}\eta \cdot \eta dx. \]

Since \( \lambda > 0 \) can be taken arbitrarily small, the latter relation may hold only if

\[ \int_{\Omega} (A^{-1}\hat{p} \cdot \eta + \hat{u}\text{div} \eta)dx - g(u_0, \eta) \geq 0. \]

But \( \eta \) is an arbitrary element of a linear manifold \( \hat{Q}_0 \), so that \(+\eta\) can be replaced by \(-\eta\) what leads to the conclusion that

\[ \int_{\Omega} (A^{-1}\hat{p} \cdot \eta + \hat{u}\text{div} \eta)dx - g(u_0, \eta) = 0 \quad \forall \eta \in \hat{Q}_0. \]
From

\[ \hat{\mathbf{L}}(\hat{\mathbf{u}}, \hat{\mathbf{p}}) \leq \hat{\mathbf{L}}(\hat{\mathbf{u}} + \hat{\mathbf{v}}, \hat{\mathbf{p}}) \quad \forall \hat{\mathbf{v}} \in \hat{\mathbf{V}} := L^2(\Omega) \]

we observe that the terms of \( \hat{\mathbf{L}} \) linear with respect to the "pressure" must vanish. Namely, we obtain

\[ \int_{\Omega} (\hat{\mathbf{v}} \text{div} \hat{\mathbf{p}} + f\hat{\mathbf{v}}) d\mathbf{x} = 0 \]

Thus, we arrive at the system

\[ \int_{\Omega} (A^{-1}\hat{\mathbf{p}} \cdot \hat{\mathbf{q}} + (\text{div}\hat{\mathbf{q}})\hat{\mathbf{u}}) d\mathbf{x} = g(\mathbf{u}_0, \hat{\mathbf{q}}) \quad \forall \hat{\mathbf{q}} \in \hat{\mathbf{Q}}_0, \quad (140) \]

\[ \int_{\Omega} (\text{div}\hat{\mathbf{p}} + f)\hat{\mathbf{v}} d\mathbf{x} = 0 \quad \forall \hat{\mathbf{v}} \in \hat{\mathbf{V}}. \quad (141) \]
We observe that now the condition

$$\text{div}\hat{\mathbf{p}} + f = 0$$

is satisfied in a ”strong” ($L_2$) sense, the Neumann type boundary condition is viewed as the essential boundary condition, and the relation

$$\hat{\mathbf{p}} = A\nabla\mathbf{u}$$

and the Dirichlet type boundary condition are satisfied in a weak sense. These properties of the DMM lead to that the respective finite dimensional formulations are better adapted to the satisfaction of the equilibrium type relations for the fluxes. This fact is important in many applications where a sharp satisfaction of the equilibrium relations is required.
The Lagrangian $\hat{L}$ also generates two functionals

$$\hat{J}(\hat{v}) := \sup_{\hat{q} \in \hat{Q}_F} \hat{L}(\hat{v}, \hat{q}) \quad \text{and} \quad \hat{l}^*(\hat{q}) := \inf_{\check{v} \in \check{V}} \hat{L}(\check{v}, \hat{q}).$$

The two corresponding variational problems are

$$\inf_{\hat{v} \in \hat{V}} \hat{J}(\hat{v}) \quad \text{and} \quad \sup_{\hat{q} \in \hat{Q}_F} \hat{l}^*(\hat{q}).$$

They are called Problems $\hat{P}$ and $\hat{P}^*$, respectively. Note that the functional $\hat{J}$ (unlike $J$) has no simple explicit form. However, we can prove the solvability of Problem $\hat{P}$ by the following Lemma.
Lemma

For any $\hat{\mathbf{v}} \in \hat{\mathbf{V}}$ and $\mathbf{F} \in L_2(\partial_2 \Omega)$ there exists $\mathbf{p}^\mathbf{v} \in \hat{Q}_F$ such that

\[
\begin{align*}
\text{div} \mathbf{p}^\mathbf{v} + \hat{\mathbf{v}} &= 0 \quad \text{in} \; \Omega, \\
\| \mathbf{p}^\mathbf{v} \| &\leq C_\Omega (\| \hat{\mathbf{v}} \| + \| \mathbf{F} \|_{\partial_2 \Omega}).
\end{align*}
\]

Proof. We know that the boundary-value problem

\[
\begin{align*}
\text{div} A \nabla \mathbf{u}^\mathbf{v} + \hat{\mathbf{v}} &= 0 \quad \text{in} \; \Omega, \\
\mathbf{u}^\mathbf{v} &= 0 \quad \text{on} \; \partial_1 \Omega, \\
A \nabla \mathbf{u}^\mathbf{v} \cdot \mathbf{n} &= \mathbf{F} \quad \text{on} \; \partial_2 \Omega
\end{align*}
\]

possesses the unique solution $\mathbf{u}^\mathbf{v} \in \mathbf{V}_0$. 
For it and the energy estimate

\[ \| \nabla u^y \| \leq C_\Omega (\| \hat{v} \| + \| F \|_{2\Omega}) \]

holds. Let \( p^y := A \nabla u^y \). We have

\[ \text{div} p^y + \hat{v} = 0. \]

Obviously, \( p^y \in \hat{Q}_F \) and, since

\[ \| p^y \|_*^2 = \int_\Omega A^{-1}(A \nabla u^y) \cdot (A \nabla u^y) \, dx = \| \nabla u^y \|^2, \]

we find that (143) also holds.

\( \square \)
By the Lemma we can easily prove the coercivity of $\hat{J}$ on $\hat{V}$. Indeed,

$$
\hat{J}(\hat{v}) \geq \hat{L}(\hat{v}, \alpha p^v) = \\
- \frac{1}{2} \|\alpha p^v\|_*^2 - \alpha \int_\Omega \hat{v}(\text{div}p^v) \, dx - \int_\Omega f \hat{v} \, dx - \int_{\partial_2 \Omega} F_0 \, ds + g(u_0, \alpha p^v) = \\
= -\frac{1}{2} \alpha^2 \|p^v\|_*^2 + \alpha \|\hat{v}\|^2 - \|f\|\|\hat{v}\| + g(u_0, \alpha p^v) - \int_{\partial_2 \Omega} F_0 \, ds.
$$

Here $|g(u_0, \alpha p^v)| \leq \alpha \|p^v\|_{\text{div}} \|u_0\|_{1,2,\Omega}$ and

$$
\|p^v\|_{\text{div}}^2 = \|p^v\|^2 + \|\text{div}p^v\|^2 \leq \frac{1}{c_1} \|p^v\|_*^2 + \|\hat{v}\|^2 \leq \\
\leq \frac{1}{c_1} C_\Omega^2 (\|\hat{v}\| + \|F\|_{\partial_2 \Omega})^2 + \|\hat{v}\|^2.
$$
Therefore
\[
\hat{J}(\hat{v}) \geq -\frac{1}{2} \alpha^2 C_{\Omega}^2 \|\hat{v}\|^2 + \alpha \|\hat{v}\|^2 + \Theta(\|\hat{v}\|) + \Theta_0,
\]
where \( \Theta(\|\hat{v}\|) \) contains the terms linear with respect to \( \|\hat{v}\| \) and \( \Theta_0 \) does not depend on \( \hat{v} \). Take \( \alpha = 1/C_{\Omega}^2 \). Then
\[
\hat{J}(\hat{v}) \geq \frac{1}{2C_{\Omega}^2} \|\hat{v}\|^2 + \Theta(\|\hat{v}\|) + \Theta_0 \rightarrow +\infty \ \text{as} \ \|\hat{v}\| \rightarrow \infty.
\]

It is not difficult to prove that the functional \( \hat{J} \) is convex and lower semicontinuous. Therefore, Problem \( \hat{P} \) has a solution \( \hat{u} \).
Corollary
Lemma implies the \textit{inf-sup} condition

\[
\inf_{\phi \in L^2(\Omega)} \sup_{\psi \in L^2(\partial_2 \Omega)} \sup_{q \in \widetilde{Q}_F} \int_\Omega \phi \text{div} q \, dx + \int_{\partial_2 \Omega} \psi q \cdot n \, ds \geq C_0 > 0.
\]
Let us now construct the dual functional $\hat{I}^*$. It is easy to see that

$$\hat{I}^*(\hat{q}) = \inf_{\hat{v}} \hat{L}(\hat{v}, \hat{q}) =$$

$$= \inf_{\hat{v}} \left\{ -\frac{1}{2} \| \hat{q} \|^2_\ast - \int\limits_{\Omega} \nabla(\text{div}\hat{q}) dx - \int\limits_{\Omega} f v dx - \int\limits_{\partial_2 \Omega} F u_0 ds + g(u_0, \hat{q}) \right\} =$$

$$= -\frac{1}{2} \| \hat{q} \|^2_\ast + g(u_0, \hat{q}) - \int\limits_{\partial_2 \Omega} F u_0 ds$$

provided that $\text{div}\hat{q} + f = 0$ (in the $L_2$-sense). In all other cases $\hat{I}^*(\hat{q}) = -\infty$. 
Recalling that \( \text{div} \hat{q} = -f \) (in \( L_2(\Omega) \)-sense), we find that the dual functional for such a case has the form

\[
\hat{I}^*(q) = -\frac{1}{2} \| \hat{q} \|^2_* + \int_{\Omega} (\nabla u_0 \cdot \hat{q} - fu_0) \, dx - \int_{\partial_2 \Omega} Fu_0 \, ds
\]

\[
= \int_{\Omega} \nabla u_0 \cdot \hat{q} \, dx - \frac{1}{2} \| \hat{q} \|^2_* - \ell(u_0),
\]

Since \( \hat{q} \in \hat{Q}_F \), we have

\[
\int_{\Omega} \nabla w \cdot \hat{q} \, dx = -\int_{\Omega} (\text{div} \hat{q}) w \, dx + \int_{\partial_2 \Omega} Fwds \quad \forall w \in V_0.
\]

we see that \( \hat{q} \) satisfies the relation

\[
\int_{\Omega} \nabla w \cdot \hat{q} \, dx = \ell(w) \quad \forall w \in V_0.
\]

In other cases, \( \hat{I}^*(\hat{q}) = -\infty \).
Thus, Problems $P^*$ and $\hat{P}^*$ coincide and are reduced to the maximization of $I^*$ on the set $Q_\ell$. This means that

$$\sup P^* = \sup \hat{P}^*.$$ 

Since the saddle point of $\hat{L}$ exists, we have

$$\hat{L}(\hat{u}, \hat{p}) = \inf \hat{P} = \sup \hat{P}^*,$$

but

$$\sup \hat{P}^* = \sup P^* = \inf P.$$ 

Thus, we infer that

$$\inf \hat{P} = \inf P.$$
Thus, we conclude that $u \in V_0 + u_0$ (minimizer of $\mathcal{P}$) also minimizes $\hat{J}$ on $\hat{V}$. Analogously, if $p \in Q_\ell$ is the maximizer of Problem $\mathcal{P}^*$, then

$$\int_{\Omega} \nabla w \cdot p \, dx = \int_{\Omega} fw \, dx + \int_{\partial\Omega} Fw \, ds \quad \forall w \in V_0.$$

From here we see that $\text{div}p + f = 0$ a.e. in $\Omega$ and, hence,

$$\int_{\Omega} (\nabla w \cdot p + (\text{div}p)w) \, dx = \int_{\partial\Omega} Fw \, ds \quad \forall w \in V_0,$$

that is $p \in \hat{Q}_F$. Thus, $p$ is also the maximizer of Problem $\hat{\mathcal{P}}^*$. The reverse statement that the solutions of $\hat{\mathcal{P}}$, $\hat{\mathcal{P}}^*$ are also the solutions of $\mathcal{P}$, $\mathcal{P}^*$ is not difficult to prove as well.
Hence, both mixed formulations have the same solution \((u, p)\) which is in fact the generalized solution of our problem.
Finite dimensional formulations

Let

\[ \hat{V}_h \subset \hat{V}, \quad \hat{Q}_{0h} \subset \hat{Q}_0 \quad \hat{Q}_{Fh} \subset \hat{Q}_F \]

A discrete analog of the dual mixed formulation is: Find \((\hat{u}_h, \hat{p}_h) \in \hat{V}_h \times \hat{Q}_{Fh}\) such that

\[ \int_{\Omega} \left( A^{-1} \hat{p}_h \cdot \hat{q}_h + \hat{u}_h \text{div} \hat{q}_h \right) dx = g(u_0, \hat{q}_h) \quad \forall \hat{q}_h \in \hat{Q}_{0h}, \tag{144} \]

\[ \int_{\Omega} (\text{div} \hat{p}_h + f) \hat{v}_h dx = 0 \quad \forall \hat{v}_h \in \hat{V}_h. \tag{145} \]
Error analysis for DMM

First we will obtain a priori error estimates for the dual mixed method and after that we will derive computable upper bounds for the quantities

\[ \| \nabla (u - u_h) \|, \| p - p_h \|_* , \| p - \hat{p}_h \|_{\text{div}}. \]
A priori error estimates for DMM

Below we will show a simple way of the derivation of projection type error estimates for the dual mixed method. By combining them with standard interpolation results, one can obtain known rate convergence estimates. A detailed exposition of this subject can be found in the above cited books. Here, we present a simplified version, which, however contains the main ideas of the a priori error analysis for the dual mixed approximations.
For the sake of simplicity we will consider the case of uniform Dirichlet boundary conditions and a constant matrix $A$. In this case, the basic system is as follows

$$\int_{\Omega} (A^{-1}\hat{p} \cdot \hat{q} + (\text{div}\hat{q})\hat{u}) \, dx = 0 \quad \forall \hat{q} \in \hat{Q}_0,$$

$$\int_{\Omega} (\text{div}\hat{p} + f)\hat{v} \, dx = 0 \quad \forall \hat{v} \in \hat{V}.$$

Since there is no Neumann part of the boundary, $\hat{Q}_F$ and $\hat{Q}_0$ coincides with $\hat{Q} := H(\Omega, \text{div})$. 
In the considered case the system of DMM is as follows

\[
\int_{\Omega} \left( A^{-1} \hat{p}_h \cdot \hat{q}_h + \hat{u}_h \text{div} \hat{q}_h \right) \, dx = 0 \quad \forall \hat{q}_h \in \hat{Q}_h,
\]

\[
\int_{\Omega} (\text{div} \hat{p}_h + f) \hat{v}_h \, dx = 0 \quad \forall \hat{v}_h \in \hat{V}_h.
\]

**Assumptions.**

(a) \( T_h \) is a regular triangulation of a polygonal domain \( \Omega \).

(b) \( \hat{V}_h = \{ v_h \in L^2 \mid v_h \in P^0(T) \quad \forall T \in T_h \} \).

(c) \( \hat{Q}_h = \{ q_h \in H(\Omega, \text{div}) \mid q_h \in RT^0(T) \quad \forall T \in T_h \} \).

(d) \( f \in P^0(T), \quad \forall T \in T_h \).
Note that under the assumptions made

\[ \text{div} p_h + f = 0 \quad \text{on any } T. \]

Indeed, this fact directly follows from the relation

\[ \int_{\Omega} (\text{div} p_h + f) \hat{v}_h \, dx = 0 \quad \forall \hat{v}_h \in \hat{V}_h. \]

Therefore \( p_h \in Q_f \).
Compatibility and stability conditions

In order to provide the stability of the discrete DM formulation we need additional assumptions. We assume that a pair of finite dimensional spaces $\hat{V}_h, \hat{Q}_h$ satisfies the following condition:

For any $\mathbf{v}_h \in \hat{V}_h$ exists $\mathbf{q}^\mathbf{v}_h \in \hat{Q}_h$ such that

\[
\text{div}\mathbf{q}^\mathbf{v}_h = \mathbf{v}_h \quad \text{(compatibility)},
\]

\[
\|\mathbf{q}^\mathbf{v}_h\| \leq C \|\mathbf{v}_h\| \quad \text{(stability)}.
\]
We will show that the above two conditions are the sufficient conditions for proving that discrete DM problem is
(a) correct (e.g., has a solution),
(b) stable,
(c) has a projection type error estimate.
Discrete Inf-Sup condition

From (146) and (147), it follows that

\[ \inf_{v_h} \sup_{q_h} \int_{\Omega} \frac{v_h \text{div} q_h \, dx}{\|v_h\|_{\text{div}} \|q_h\|_{\text{div}}} \geq C > 0 \]

Indeed,

\[ \sup_{q_h \in \hat{Q}_h} \int_{\Omega} \frac{v_h \text{div} q_h \, dx}{\|v_h\|_{\text{div}} \|q_h\|_{\text{div}}} \geq \int_{\Omega} \frac{v_h \text{div} q_h' \, dx}{\|v_h\|_{\text{div}} \|q_h'\|_{\text{div}}} = \frac{\|v_h\|}{\|q_h\|_{\text{div}}} \geq \frac{1}{\sqrt{1 + C^2}}. \]

Now, we refer to known results on the solvability of DMM, that can be summarized as follows: if the triangulations are "regular" and the discrete Inf-Sup condition holds, then the discrete formulation has a unique solution.
Projection type estimate for the dual problem

Since \( p \) is a maximizer, i.e.,

\[
-\frac{1}{2} \| q \|_2^2 \leq -\frac{1}{2} \| p \|_2^2 \quad \forall q \in Q_f,
\]

we find that

\[
\int_{\Omega} A^{-1} p \cdot q \, dx = 0 \quad \forall q \in Q_0,
\]

where \( Q_0 \) is the space of solenoidal functions. Therefore, for any \( q \in Q_f \),

\[
\frac{1}{2} \| q - p \|_2^2 = \frac{1}{2} \| q \|_2^2 - \frac{1}{2} \| p \|_2^2 + \int_{\Omega} A^{-1} p \cdot (p - q) \, dx =
\]

\[
= \frac{1}{2} \| q \|_2^2 - \frac{1}{2} \| p \|_2^2.
\]
Let $Q_{fh} = Q_f \cap \hat{Q}_h$. Note that $p_h \in Q_{fh}$ is also the maximizer of $-\frac{1}{2} \| q_{fh} \|_*^2$ on $Q_{fh}$, so that

$$\frac{1}{2} \| p_h - p \|_*^2 = \frac{1}{2} \| p_h \|_*^2 - \frac{1}{2} \| p \|_*^2 \leq \frac{1}{2} \| q_{fh} \|_*^2 - \frac{1}{2} \| p \|_*^2 = \frac{1}{2} \| q_{fh} - p \|_*^2 \quad \forall q_{fh} \in Q_{fh}.$$ 

Thus, we arrive at the first projection estimate

$$\| p - p_h \|_* \leq \inf_{q_{fh} \in Q_{fh}} \| p - q_{fh} \|_* . \quad (148)$$
However, this projection error estimate has an obvious drawback. It is applicable only for a very narrow class of approximations: conforming (internal) approximations of the set $Q_f$.

To obtain an estimate for a wider class, we first derive one auxiliary result.
A Modified DM problem

Take $\tilde{f} = \text{div}(\hat{q}_h - p)$ where $\hat{q}_h \in \hat{Q}_h$ and solve the modified DM problem

$$
\int_{\Omega} \left( A^{-1} \hat{p}_h \cdot \hat{q}_h + \hat{u}_h \text{div}\hat{q}_h \right) dx = 0 \quad \forall \hat{q}_h \in \hat{Q}_0h, \quad (149)
$$

$$
\int_{\Omega} (\text{div}\hat{p}_h + \tilde{f})\hat{v}_h dx = 0 \quad \forall \hat{v}_h \in \hat{V}_h. \quad (150)
$$

Under the assumptions made $\tilde{f} \in P^0(T)$, the above DM problem is solvable, and

$$
\| \hat{p}_h \|_\ast^2 + \int_{\Omega} \hat{u}_h \text{div}\hat{p}_h dx = 0,
$$

$$
\| \hat{p}_h \|_\ast^2 \leq \| \hat{u}_h \| \| \text{div}\hat{p}_h \| = \| \hat{u}_h \| \| \tilde{f} \|
$$
From here, we observe that

\[ c_1 \| \hat{p}_h \|^2 \leq \| \hat{p}_h \|^2 \leq \| \hat{u}_h \| \| \hat{f} \|. \quad (151) \]

By (146) and (147) we conclude that for \( \hat{u}_h \) we can find \( \bar{q}_h \) in \( \hat{Q}_h \) such that

\[ \text{div} \bar{q}_h + \hat{u}_h = 0 \quad \text{and} \quad \| \bar{q}_h \| \leq C \| \hat{u}_h \| \]

Use \( \bar{q}_h \) in the first identity (149). We have,

\[ \int_{\Omega} \left( A^{-1} \hat{p}_h \cdot \bar{q}_h + \hat{u}_h \text{div} \bar{q}_h \right) dx = 0 \]

Thus,

\[ \| \hat{u}_h \|^2 = \int_{\Omega} \hat{u}_h \text{div} \bar{q}_h \leq \| \hat{p}_h \| * \| \bar{q}_h \| * \leq \]

\[ \leq c_2 \| \hat{p}_h \| * \| \bar{q}_h \| \leq c_2 C \| \hat{p}_h \| * \| \hat{u}_h \|. \]
We observe that

\[ \| \hat{u}_h^f \| \leq \bar{c}_2 C \| \hat{p}_h^f \|_\ast. \] (152)

Now, we use (151) and obtain

\[ \| \hat{p}_h^f \|_\ast \leq \| \hat{u}_h^f \| \| \hat{f} \| \leq \bar{c}_2 C \| \hat{p}_h^f \|_\ast \| \hat{f} \|. \]

so that

\[ \bar{c}_1 \| \hat{p}_h^f \| \leq \| \hat{p}_h^f \|_\ast \leq \bar{c}_2 C \| \hat{f} \|. \] (153)

Hence,

\[ \| \hat{p}_h^f \|_{\text{div}}^2 = \| \hat{p}_h^f \|^2 + \| \text{div} \hat{p}_h^f \|^2 \leq \left( 1 + \frac{c_2^2}{c_1^2} C^2 \right) \| \hat{f} \|^2. \] (154)
We note that the estimates (152), (153), and (154) show that the modified DM problem is stable, i.e. its solutions \((\hat{p}_h^f, \hat{u}_h^f)\) are bounded by the problem data uniformly with respect to \(h\).

If replace \(\tilde{f}\) by \(f\), then we can derive the same stability estimate for the functions \((\hat{p}_h, \hat{u}_h)\) that present an approximate solution of the original DM problem.
Projection estimates for fluxes

Now, we return to the projection error estimates. As we have seen

\[ \| p - p_h \| \star \leq \inf_{q_h \in Q_h} \| p - q_h \|. \]

This estimate did not satisfy us because the set \( Q_h \) is difficult to construct. To avoid this drawback, we apply the following procedure.

Let \( \eta_h = \hat{p}_h^f + \hat{q}_h \), where \( \hat{q}_h \) is an arbitrary element of \( \hat{Q}_h \).

We have,

\[
\text{div} \eta_h = \text{div} \hat{p}_h^f + \text{div} \hat{q}_h = -\tilde{f} + \text{div} \hat{q}_h = \\
= \text{div}(p - \hat{q}_h) + \text{div} \hat{q}_h = \text{div} p = -f.
\]

Therefore, \( \eta_h \in Q_f \)
Now, we recall the projection inequality and substitute in it $\eta_h$:

\[
||p - p_h||_* \leq ||p - \eta_h||_* = ||p - \hat{p}^f_h - \hat{q}_h||_* \leq \leq ||p - \hat{q}_h||_* + ||\hat{p}_h||_*. \tag{155}
\]

Note that in the case considered $\text{div}(p - p_h) = 0$, so that

\[
||p - p_h||_{\text{div}} = ||p - p_h|| \leq \frac{1}{\bar{c}_1} ||p - p_h||_*. \tag{156}
\]

Therefore,

\[
||p - p_h||_{\text{div}} \leq \frac{1}{\bar{c}_1} (||p - \hat{q}_h||_* + ||\hat{p}_h||_*) \leq \leq \frac{1}{\bar{c}_1} (||p - \hat{q}_h||_* + \bar{c}_2 C ||\tilde{f}||). \tag{153}
\]

But $\tilde{f} = \text{div}(p - \hat{q}_h)$. 
Thus, we arrive at the estimate

\[ \| p - p_h \|_{\text{div}} \leq \frac{1}{\bar{c}_1} (\| p - \hat{q}_h \| \ast + \bar{c}_2 C \| \text{div}(p - \hat{q}_h) \|) \quad \forall \hat{q}_h \in \hat{Q}_h. \]

And, therefore,

\[ \| p - p_h \|_{\text{div}} \leq \bar{C}_p \inf_{\hat{q}_h \in \hat{Q}_h} \{ \| p - \hat{q}_h \| \ast + \| \text{div}(p - \hat{q}_h) \| \}. \quad (157) \]

where \( \bar{C}_p \) depends on \( C, \bar{c}_1, \) and \( \bar{c}_2 \) and does not depend on \( h \).
Projection type error estimates for $\hat{u} - \hat{u}_h$

We have

$$\int_{\Omega} \left( A^{-1} \hat{p}_h \cdot \hat{q}_h + \hat{u}_h \text{div} \hat{q}_h \right) dx = 0 \quad \forall \hat{q}_h \in \hat{Q}_h.$$ 

Since $\hat{Q}_h \subset Q$, we also have

$$\int_{\Omega} \left( A^{-1} p \cdot \hat{q}_h + u \text{div} \hat{q}_h \right) dx = 0.$$ 

From here, we observe that

$$\int_{\Omega} \left( A^{-1} (\hat{p}_h - p) \cdot \hat{q}_h + (\hat{u}_h - u) \text{div} \hat{q}_h \right) dx = 0 \quad \forall \hat{q}_h \in \hat{Q}_h.$$
Denote

\[ [u]_T = \frac{1}{|T|} \int_T u \, dx, \quad [u]_h(x) = [u]_{T_i} \text{ if } x \in T_i. \]

Since \( \text{div} \hat{q}_h \) is constant on each \( T_i \), we rewrite the relation as follows:

\[ \int_{\Omega} \left( A^{-1}(\hat{p}_h - p) \cdot \hat{q}_h + (\hat{u}_h - [u]_h) \text{div} \hat{q}_h \right) dx = 0 \quad \forall \hat{q}_h \in \hat{Q}_h. \]

Note that \([u]_h \in \hat{V}_h \) and therefore \( \bar{u}_h := \hat{u}_h - [u]_h \in \hat{V}_h \) Now, we exploit the compatibility and stability conditions (146) and (147) again. For \( \bar{u}_h \) one can find \( q'_h \in \hat{Q}_h \) such that

\[ \text{div} q'_h + \bar{u}_h = 0 \text{ and } \|q'_h\| \leq C\|\bar{u}_h\|. \]
Let us use this function $\mathbf{q}_h'$ in the integral relation. We have

$$\int_{\Omega} \left( \mathbf{A}^{-1} (\hat{\mathbf{p}}_h - \mathbf{p}) \cdot \mathbf{q}_h' + \bar{\mathbf{u}}_h \text{div} \mathbf{q}_h' \right) \, d\mathbf{x} = 0.$$ 

From here, we conclude that

$$\|\bar{\mathbf{u}}_h\|^2 = \left| \int_{\Omega} \mathbf{A}^{-1} (\hat{\mathbf{p}}_h - \mathbf{p}) \cdot \mathbf{q}_h' \right| \leq$$

$$\leq \| \hat{\mathbf{p}}_h - \mathbf{p} \|_* \| \mathbf{q}_h' \|_* \leq C \bar{c}_2 \| \hat{\mathbf{p}}_h - \mathbf{p} \|_* \|\bar{\mathbf{u}}_h\|.$$ 

Thus,

$$\|\bar{\mathbf{u}}_h\| = \| [\mathbf{u}]_h - \hat{\mathbf{u}}_h \| \leq C \bar{c}_2 \| \hat{\mathbf{p}}_h - \mathbf{p} \|_*.$$
We have
\[ \| u - \hat{u}_h \| \leq \| u - [u]_h \| + \| [u]_h - \hat{u}_h \| \leq \| u - [u]_h \| + C \bar{c}_2 \| \hat{p}_h - p \|_* \]

Note that by the definition of \([u]_h\)
\[ \| u - [u]_h \| \leq \| u - v_h \| \quad \forall v_h \in \hat{V}_h. \]

From here, we observe that
\[ \| u - \hat{u}_h \| \leq C \bar{c}_2 \| \hat{p}_h - p \|_* + \inf_{v_h \in \hat{V}_h} \| u - v_h \| \]

Recall (156) and observe that
\[ \| p - p_h \|_* \leq \| p - \hat{q}_h \|_* + \| \hat{p}_h \|_* \leq \| p - \hat{q}_h \|_* + \bar{c}_2 \| \text{div}(p - \hat{q}_h) \|. \]
Then, we arrive at the projection type error estimate for the primal variable

$$\| u - \hat{u}_h \| \leq \leq C_{u} \inf_{\hat{q}_h \in \hat{Q}_h} \left\{ \| p - \hat{q}_h \|_\ast + \| \text{div}(p - \hat{q}_h) \| + \right. $$

$$+ \left. \inf_{v_h \in \hat{V}_h} \| u - v_h \| \right\}, \quad (158)$$

where $C_u$ depends on $C$, $\bar{c}_1$, and $\bar{c}_2$ and does not depend on $h$. Estimates (157) and (158) lead to a qualified a priori convergence estimates provided that the solution possesses proper regularity.
Now, we proceed to the derivation of **functional type a posteriori error estimates** for the Primal Mixed and Dual Mixed methods.

Our analysis follows the lines of the paper

Our aim is to find the difference between \((u, p)\) and \((v, q)\) in the respective energy norm, e.g. in the norm of the space \(V \times U\).
A posteriori error estimates for the mixed formulation are based on the relation that we have already derived:

$$\|\mathbf{p} - \mathbf{q}\|^2 + \|\nabla(\mathbf{u} - \mathbf{v})\|^2 = 2(J(\mathbf{v}) - I^*(\tilde{\mathbf{q}})),$$

where $\tilde{\mathbf{q}} \in Q_f$ and $\mathbf{v} \in V_0 + \mathbf{u}_0$. 
Since the difference of the functionals in the right–hand side can be estimated by the known way, we arrive at the estimate

\[
\| p - \tilde{q} \|_*^2 + \| \nabla (u - v) \|^2 \leq 2(1 + \beta) D(\nabla v, y) \\
+ \left(1 + \frac{1}{\beta}\right) C^2 \left(\| \text{div} y + f \|^2 + \| y \cdot n - F \|_{\partial^2 \Omega}^2 \right), \tag{159}
\]

where \( y \in \hat{Q}^+, \tilde{q} \in Q_f \) and \( v \in V_0 + u_0 \) are arbitrary functions and \( \beta \) is any positive number.
Thus, for the error in the primal variable we have

\[ \| \nabla (u - u_h) \|^2 \leq 2(1 + \beta)D(\nabla u_h, y) + \left( 1 + \frac{1}{\beta} \right) C^2 \left( \| \text{div} y + f \|^2 + \| y \cdot n - F \|^2_{\partial_2 \Omega} \right). \]  

(160)

where \( C \) is a constant in the inequality

\[ \| w \|^2 + \| w \|^2_{\partial_2 \Omega} \leq C^2 \| \nabla w \|^2 \quad \forall w \in V_0 . \]
A posteriori estimate for the dual variable

Error estimates for the dual variable in the dual energy norm $\| \cdot \|_*$ can be obtained by the arguments similar to those used above. Let $q \in Y^*$ be an approximation of $p$. For any $\tilde{q} \in Q^*_f$, we obtain (from the triangle inequality and Young inequalities with $\gamma > 0$)

$$\| q - p \|_*^2 \leq (1 + \gamma) \| q - \tilde{q} \|_*^2 + \left( 1 + \frac{1}{\gamma} \right) \| \tilde{q} - p \|_*^2.$$ 

Use the fact that $\| \tilde{q} - p \|_*^2 \leq 2 (J(v) - I^*(\tilde{q}))$. 
Therefore, for any \( w \in V_0 + u_0 \), we have

\[
\| q - p \|_*^2 \leq (1 + \gamma) \| q - \tilde{q} \|_*^2 + 2 \left(1 + \frac{1}{\gamma} \right) \left( J(u) - I^*(\tilde{q}) \right) \leq (1 + \gamma) \| q - \tilde{q} \|_*^2 + 2 \left(1 + \frac{1}{\gamma} \right) \left( J(w) - I^*(\tilde{q}) \right) =
\]

Recall that

\[
J(w) - I^*(\tilde{q}) \leq (1 + \beta) D(\nabla w, y) + \left(1 + \frac{1}{\beta} \right) \frac{1}{2} \| q - \tilde{q} \|_*^2
\]

so that the right-hand side is estimated by

\[
(1+\gamma) \left(1 + \frac{1}{\gamma} + \frac{1}{\beta \gamma} \right) d_{Q_f}^2(q) + 2(1 + \beta) \left(1 + \frac{1}{\gamma} \right) D(\nabla w, q).
\]
If \( q \in U \), then \( d_{Q_f} \) is given by the negative norm and we obtain

\[
\| q - p \|^2 \leq (1 + \gamma) \left( 1 + \frac{1}{\gamma} + \frac{1}{\beta \gamma} \right) \| f + \text{div}q \| + \\
+ (1 + \beta) \left( 1 + \frac{1}{\gamma} \right) D(\nabla w, q).
\] (161)

If \( q \in Q \) then we have (for the Dirichlét problem)

\[
\| q - p \|^2 \leq (1 + \gamma) \left( 1 + \frac{1}{\gamma} + \frac{1}{\beta \gamma} \right) C_\Omega \| f + \text{div}q \| + \\
+ (1 + \beta) \left( 1 + \frac{1}{\gamma} \right) D(\nabla w, q).
\] (162)

This estimate holds for any positive parameters \( \beta, \gamma \), and any \( \mathbf{w} \in V_0 + u_0 \). Here \( \mathbf{w} \) is a ”free” function in \( V_0 + u_0 \). This ”freedom” can be used to make the estimate sharper.
Application of (161) to DM approximations leads (after optimization with respect to scalar parameters) to the estimate

\[
\| p - p_h \|_* \leq \sqrt{2D}^{1/2} (\nabla w, y) + \| y - p_h \|_* \\
+ 2C \left( \| \text{div} y + f \|^2 + \| y \cdot n - F \|^2 \right)^{1/2}.
\] (163)

Here \( w \) is an arbitrary function from \( V_0 + u_0 \) and \( y \) is an arbitrary function from \( \hat{Q}^+ \). If \( y = A \nabla u \) and \( w = u \), then the right-hand side of (163) coincides with the left-hand side, i.e. is exact in the sense that there exist such ”free variables” that the inequality holds as the equality.
A directly computable upper bound of \( \| p - p_h \|_* \) is given by (163), if we set
\[
v = u_h, \quad \text{and} \quad y = G_h p_h,
\]
where \( G_h : Q_h \to \hat{Q}^+ \) is a certain projection operator (some examples such operators has been already discussed in the previous lectures). We have
\[
\| p - p_h \|_* \leq \sqrt{2} D^{1/2} (\nabla u_h, G_h p_h) + \| G_h p_h - p_h \|_* + 2C \left( \| \text{div} G_h p_h + f \|^2 + \| G_h p_h \cdot n - F \|^2 \right)^{1/2}.
\]
Projection from $Q_h$ onto $\hat{Q}^+$

If $p_h$ is a piecewise-constant vector field on a simplicial mesh $\mathcal{T}_h$, then, Raviart–Thomas elements (e.g., $RT^0$–elements) can be used in order to define the mapping $G$.

Assume that the $\Omega$ has a polygonal boundary, and the latter is exactly matched by the triangulation $\mathcal{T}_h$. Let $T_i$ and $T_j$ be two neighboring simplexes with the common edge $E_{ij}$. Let $q_h$ be a piecewise constant vector-valued function that has the values $q_i$ and $q_j$ on $T_i$ and $T_j$ respectively. Let $E_{ij}$ be the common edge with the unit normal $n_{ij}$ oriented from $T_i$ to $T_j$ if $i > j$.

How to define the common value $\tilde{q}_{ij} \cdot n_{ij}$ on $E_{ij}$?
One possible option is as follows:

\[ \tilde{q}_{ij} \cdot n_{ij} = \frac{1}{2} (q_i + q_j) \cdot n_{ij}, \]

Another option is

\[ \tilde{q}_{ij} \cdot n_{ij} = \frac{|T_i| q_i + |T_j| q_j}{|T_i| + |T_j|} \cdot n_{ij}, \]

where \(|T_i|\) and \(|T_j|\) are the areas of \(T_i\) and \(T_j\). We repeat this procedure for all internal edges of \(\mathcal{T}_h\).

If \(E_{i0} \in \partial_1 \Omega\), then we set \(\tilde{q}_{i0} \cdot n_{i0} = q_{i0} \cdot n_{i0}\). If \(E_{i0} \in \partial_2 \Omega\), then

\[ \tilde{q}_{i0} \cdot n_{i0} = \frac{1}{|E_{i0}|} \int_{E_{i0}} F \, ds. \]

Here \(|E_{i0}|\) is the length of the edge \(E_{i0}\).
Thus, all the normal components $\tilde{q}_{ij} \cdot n_{ij}$ on internal and external edges are defined. By prolongation inside all $T_i$, with the help of $RT_0$-approximations we obtain the function a piecewise affine function, which has continuous normal components at all the edges and piecewise constant normal components on $\partial \Omega$.

Therefore, we, in fact, have constructed a mapping $q_h \rightarrow \tilde{q}_h$ such that

$$\tilde{q}_h = \mathcal{G}_h q_h \in \hat{Q}^+.$$
An a posteriori estimate for the flux $\hat{\mathbf{p}}_h$ readily follows from the general estimate

$$\frac{1}{2} \| y - p \|_*^2 \leq (1 + \gamma) \left( 1 + \frac{1}{\gamma} + \frac{1}{\beta \gamma} \right) \| f + \text{div} y \|^2 +$$

$$+ (1 + \beta) \left( 1 + \frac{1}{\gamma} \right) D(\nabla w, y).$$

We set $y = \hat{\mathbf{p}}_h \in \hat{Q}^+$. Since $\hat{\mathbf{p}}_h$ is a piecewise polynomial function, it has a summable trace on $\partial_2 \Omega$. Then, we estimate $\| f + \text{div} y \|$ from above in the same way as before.
Minimization with respect to $\gamma$ and $\beta$ leads to the estimate

$$\| p - \hat{p}_h \| \leq \sqrt{2D}^{1/2} (\nabla w, \hat{p}_h) + 2C \left( \| \text{div} \hat{p}_h + f \|^2 + \| \hat{p}_h \cdot n - F \|_{\partial \Omega}^2 \right)^{1/2},$$

where $w$ is an arbitrary function from $V_0 + u_0$. 
Assume that $\Omega$ is a polygonal domain decomposed into a regular collection of simplexes. If $\hat{p}_h$ is constructed by means of $RT_0$-elements, then

$$
\int_{\Omega} (\text{div}\hat{p}_h + f)w_h\,dx = 0 \quad \forall w_h \in \hat{V}_h \subset \hat{V},
$$

where the subspace $\hat{V}_h$ contains piecewise constant functions.

Therefore, on each element $T_i$

$$
\text{div}\hat{p}_h = -\frac{1}{|T_i|} \int_{T_i} f\,dx.
$$
Let us define by $[f]$ the function whose values on $T_i$ coincide with the mean values of $f$ on $T_i$. It is clear that $[f] \in \hat{V}_h$ Then, we have

$$\text{div} \hat{p}_h = -[f] \quad \text{on every} \quad T_i.$$ 

Estimate (165) is valid for any approximate flux $\hat{p}_h$ from $\hat{Q}^+$. If $\hat{p}_h$ belongs to the narrower set $\hat{Q}_F$ (as, e.g., it would be in the discrete dual mixed method if $f = [f]$ and pure Dirichlet conditions ) then the last norm in (165) would be identically zero.

It cannot, however, be expected, when $\hat{p}_h$ is constructed in the space $RT_0$, unless the function $F$ is a constant on $\partial_2 \Omega$. 
Remark. The problem of taking into account the essential boundary condition for the flux variable

\[ \hat{p} \cdot n = F \quad \text{on} \quad \partial_2 \Omega \]

in the dual mixed method is not at all easy and, usually, leads to a non-conforming approximation \( \hat{p}_h \)
However, (165) still works for such (nonconforming) approximations of the flux!
One simple nonconforming version of the discrete dual method, particularly suited for the lowest-order Raviart-Thomas approximation is as follows. Instead of requiring $\hat{p}_h \in \hat{Q}_F$, we impose a weaker condition

$$\hat{p}_h \cdot n|_{E_{i0}} = \frac{1}{|E_{i0}|} \int_{E_{i0}} F \, ds$$

(167)

on every edge $E_{i0} \in \partial_2 \Omega$.

If now we denote by $[F]$ the piecewise constant function defined on the set of edges forming $\partial_2 \Omega$ and whose value on every edge $E_{i0} \in \partial_2 \Omega$ is equal to the mean value of $F$ on that edge, we can write that $\hat{p}_h \cdot n = [F]$ for all $E_{i0} \in \partial_2 \Omega$. 
In this case, **nonconformity errors will be automatically accounted in the functional a posteriori estimate** \((165)\). Indeed, we obtain

\[
|| p - \hat{p}_h || \leq \sqrt{2}D^{1/2}(\nabla v, \hat{p}_h) + 2C \left( || f - [f] ||^2 + || F - [F] ||^2_{\partial \Omega} \right)^{1/2} . \quad (168)
\]
How to choose in (168) the function $w \in V_0 + u_0$.

The simplest way is to use the function $\hat{u}_h \in \hat{V}_h$ available from the solution of the discrete dual mixed problem and to construct a suitable projection operator $P_h : \hat{V}_h \to V_0 + u_0$. Again, the projection can be easily accomplished with a simple averaging.

**Projection from $\hat{V}_h$ onto $V_0 + u_0$.**

In order to find $v \in V_0 + u_0$, it is sufficient to find $w \in V_0$ in the representation $v = w + u_0$ (the function $u_0$ is given). Using the computed piecewise-constant function $\hat{u}_h$, we define $w_h \in V_0$ as follows.
We set

\[
wh(x_k) = \frac{\sum_{s=1}^{N_k} |T_s^{(k)}| \cdot uh |T_s^{(k)}|}{\sum_{s=1}^{N_k} |T_s^{(k)}|} - u_0(x_k)
\]  

(169)

for any internal node \(x_k\) and when \(x_k \in \partial_2 \Omega\). Here \(T_s^{(k)}\), \(s = 1, N_k\), are the elements containing the vertex \(x_k\), and we have assumed that the function \(u_0\) has a sufficient regularity, so that its point values are defined.

If the node \(x_k \in \partial_1 \Omega\), we simply set \(wh(x_k) = 0\).

Thus, using the nodal values of \(wh\) and the piecewise-linear continuous finite element approximation on the mesh \(T_h\) we define the function

\[
wh + u_0 = P_h \hat{uh} \in V_0 + u_0.
\]
Hence, from (168) one obtains

\[ c_1 \| \mathbf{p} - \mathbf{\hat{p}}_h \| \leq \| \mathbf{p} - \mathbf{\hat{p}}_h \| \leq \sqrt{2D^{1/2} \langle \nabla (\mathcal{P}_h \mathbf{u}_h), \mathbf{\hat{p}}_h \rangle + 2C \left( \| f - [f] \|^2 + \| F - [F] \|_{\partial_2 \Omega}^2 \right)^{1/2} } , \]  

which, together with the obvious relation

\[ \| \text{div}(\mathbf{p} - \mathbf{\hat{p}}_h) \| = \| -f - \text{div}\mathbf{\hat{p}}_h \| = \| f - [f] \| \]

leads to the upper bound for \( \| \mathbf{\hat{p}} - \mathbf{\hat{p}}_h \| \text{div} \):
Theorem

Let \((\hat{u}, \hat{p}) \in \hat{V} \times \hat{Q}_F\) be the exact solution of the dual mixed problem and 
\((\hat{u}_h, \hat{p}_h) \in \hat{V}_h \times \hat{Q}_{Fh}\) the solution of the discrete dual mixed problem with \(\hat{Q}_{Fh}\) being the Raviart-Thomas space \(RT^0\).

Then, the following estimate holds true:

\[
\|\hat{p} - \hat{p}_h\|_{\text{div}} \leq \| A \nabla (P_h \hat{u}_h) - \hat{p}_h \|_* + (2C + 1)\|f - [f]\| + 2C\|F - [F]\|_{\partial \Omega}, \quad (171)
\]

where \(P_h : \hat{V}_h \rightarrow V_0 + u_0\) is the projection (averaging) operator introduced above and \([f]\) and \([F]\) are the averaged functions.

Remark. The first and the second terms in (171), being computed elementwise, can serve as local error indicators.
A sharper estimate can be obtained by the minimization of the Majorant with respect to $v$. Here, we can restrict ourselves to certain subspace $V_h$, i.e.,

\[ \| \hat{p} - \hat{p}_h \|_{\text{div}} \leq \inf_{v_h \in V_h} \| A \nabla (v_h) - \hat{p}_h \|_* + (2C + 1) \| f - [f] \| + 2C \| F - [F] \|_{\partial \Omega}. \] (172)
By (160) we can also the squared norm of the error of the averaged solution \( P_h \hat{u}_h \) using the computed flux approximation \( \hat{p}_h \):

\[
\| \nabla (u - P_h \hat{u}_h) \|^2 \leq 2(1 + \beta) D(\nabla (P_h \hat{u}_h), \hat{p}_h) + \left( 1 + \frac{1}{\beta} \right) C^2 (\| f - [f] \|^2 + \| F - [F] \|^2_{\partial_2 \Omega}),
\]

(173)

where \( \beta > 0 \) is an arbitrary number that can be used to minimize the right-hand side of (173) and to obtain the estimate for the norm of the error.

A sharper estimate may be obtained, if one spends some time on the minimization of the right-hand side of (173) with respect to the dual variable \( y \) over some finite-dimensional subspace of \( \hat{Q}^+ \).
Remark.
If one has the solutions of both the primal and the dual mixed problems, the flux approximation $\hat{p}_h$ can be substituted into (160) to immediately yield the error estimate for the primal variable (which is the most important in the primal mixed method), while the approximation $u_h$ can be used in (171) to bring the error estimate for the dual variable (which is the most important in the dual mixed method).
MIXED FEM ON DISTORTED MESHES
The Plan

1. Approximations on distorted meshes
2. Inf-sup condition
3. A priori rate convergence estimates
4. A posteriori estimates
Distorted meshes may arise by several ways:

- Forcibly, due to the form of the given data;
- In the process of mesh refinement;
- In the process of adaptation to physical structure (e.g. layers of different materials)
Distorted mesh in 2D
Distorted mesh in 3D
How to work with such meshes?

**Straightforward way:**
Construct a regular mesh composed of standard elements that contains the given distorted one and solve the problem:

**Drawback:**
The problem obtained may have a very large dimension

We consider another *modus operandi* that is based upon a certain *aggregation procedure and reduction of some degrees of freedom*. 
Basic problem

Principal ideas of the approach we discuss on the paradigm of the classical problem

\[-\Delta u = f, \quad \text{in } \Omega\]  
\[\frac{\partial u}{\partial \nu} = 0 \quad \text{on } \partial \Omega,\]  
\(\Omega\) is a bounded connected polygonal (polyhedral) domain in \(\mathbb{R}^d\) \((d = 2, 3)\), where \(\nu\) is the outward unit normal vector to the boundary \(\partial \Omega\) and it is assumed that

\[f \in L_2(\Omega), \quad \int_{\Omega} f \, dx = 0.\] 

However, the approach can be extended to problems with the elliptic operator \(\text{div}A\nabla\) and other types of boundary conditions.
To introduce a minimax formulation of the problem (174)—(175), we define the space of square integrable functions with zero mean

\[ V(\Omega) := \left\{ v \in L_2(\Omega) \mid \int_{\Omega} v \, dx = 0 \right\}, \]

for the primal variable \( u \) and the set

\[ Q(\Omega) := \{ q \in H(\Omega, \text{div}) \mid q \cdot \nu = 0 \text{ on } \partial \Omega \}, \]

for the dual variable \( p \), where the boundary condition is understood in a generalized sense and \( H(\Omega, \text{div}) \) is the Hilbert space of vector–valued functions with the scalar product and the norm defined by the relations

\[ (p, q) := \int_{\Omega} (p \cdot q + \text{div} p \cdot \text{div} q) \, dx, \quad \|p\|_{\text{div}, \Omega} := \sqrt{(p, p)}. \]
On $V \times Q$, we define the Lagrangian

$$L(v, q) := -\int_{\Omega} \left( v \text{div} q + \frac{1}{2} |q|^2 + f v \right) \, dx.$$ 

As we have seen, the saddle–point problem: find $(u, p) \in V(\Omega) \times Q(\Omega)$ such that

$$L(u, q) \leq L(u, p) \leq L(v, p) \quad \forall v \in V, q \in Q$$

has a unique solution, which satisfies the equations

$$\int_{\Omega} (\text{div} p + f) w \, dx = 0 \quad \forall w \in V(\Omega), \quad (177)$$

$$\int_{\Omega} (p \cdot q + u \text{div} q) \, dx = 0 \quad \forall q \in Q(\Omega). \quad (178)$$
Discrete problems

Let \( T_h \) be a partitioning of \( \Omega \) into polygonal (polyhedral) cells \( \Pi_s \), \( s = 1, 2, \ldots, N \), \( h \to 0 \) as \( N \to +\infty \).

We assume that
(a) partitioning is conforming in the sense that interfaces \( E_{st} \) between cells \( \Pi_s \) and \( \Pi_t \) are straight segments for \( d = 2 \) and simply connected polygons for \( d = 3 \)
(b) partitioning is quasiuniform and the cells are regularly shaped. The first assumption means that there exist two positive numbers \( \alpha_1 \) and \( \alpha_2 \) such that

\[
\alpha_1 N^{-d} \leq \text{diam}(\Pi_s) \leq \alpha_2 N^{-d}, \quad s = 1, 2, \ldots, N.
\]  \hspace{1cm} (179)

The second means that every cell \( \Pi_s \) of \( T_h \) can be partitioned into \( n_s \) regularly shaped triangles (\( d = 2 \)), or tetrahedrons (\( d = 3 \)), and \( \max_s n_s \leq \text{const} \).
We analyze samplings where the degrees of freedom represent normal components of the vector field on the edges (interfaces) between cells/subdomains.

**Figure:** Distorted polygonal mesh
Elements of a distorted mesh in 2D
Elements of a distorted mesh in 2D
Denote by $E_{st}$ the common edge of subdomains $n_s$ and $n_t$ and by $\nu_{st}$ the unit normal vector to this edge oriented such that it is external to $n_s$ if $s < t$ and external to $n_t$ in the opposite case. The set of all edges we denote by $E_h$. The field is approximated by the quantities $q_{st}$ defined on each $E_{st} \in E_h$ (see Figure 1). The value of $q_{st}$ represents the normal component of the vector field on the edge $E_{st}$. All these quantities form the set

$$q(T_h) := \{q_{st} \mid q_{st} \text{ is defined on } E_{st} \in E_h\}.$$ 

Besides, for each $n_s$ we define a number $V_s$. These numbers form a piecewise constant approximation of the scalar–valued function $v_h$, i.e.

$$v_h \in V_h := \{v \in V(\Omega) \mid v \in P^0(n_s) \text{ for any } n_s\},$$

where $P^0$ denotes the set of zero order polynomials.
In general, there are various finite dimensional formulations that can be established on the basis of this set of parameters. We consider the one based on the "conformity concept" and certain extension operators that transform $q \in q(\mathcal{S}_h)$ to a function in $H(\Omega, \text{div})$. For this purpose, we construct a linear continuous mapping $P_\Omega : q \rightarrow P_\Omega q$ such that

$$Q = P_\Omega q \in H(\Omega, \text{div}) \quad \forall q \in q(\mathcal{S}_h).$$

Then, the respective finite dimensional scheme readily follows from the functional formulation, if the space $Q(\Omega)$ is replaced by the image space of the operator $P_\Omega$, which we denote by $Q_h(\Omega)$. 
To define $P_\Omega$ we need first to present a suitable way of extension for a cell $n$. Let

$$q(n) := \{q_{st} \mid q_{st} \text{ is defined on } E_{st} \subset \partial n\}$$

be the set of normal components of the flux on the edges of $n$.

Figure: Polygonal cell with normal components of the flux
On \( \Pi \) we define the *cell extension operator*

\[
\mathbb{P}_n : \mathbb{Q}(n) \rightarrow \mathbb{H}(n, \text{div}),
\]

which maps the set of normal components of the flux given on \( \partial n \) to a function \( Q_n = \mathbb{P}_n q(n) \) defined on \( n \). This operator must be linear and satisfy the following conditions:

(a) \( \text{div} Q_n \in P^0(n) \),

(b) \( Q_n \) is piecewise affine on \( n \),

(c) \[
\int_n \text{div} Q_n \, dx = \sum_{E_{st} \in \partial n} q_{st} |E_{st}|
\]
Comment: why special $Q_h$ and $V_h$ should be used?

A cell may have a complicated form, but it is ”small” so that on each cell we can approximate the pressure $v$ by a constant, i.e., the first space is

$$V_h := \{v_h \in V = L^2(\Omega) \mid v_h \in P^0(E^i)\},$$

How then $q_h \in H(\Omega, \text{div})$ should be presented on a distorted cell?

It is based on the condition

$$\text{div}q_h = \text{const} \quad \text{on } E^i$$
Motivation

1. Approximations $q_h$ and $v_h$ are compatible in the sense that $\text{div} q_h \in V_h$. This fact is very important in the stability and convergence analysis.
2. Also, we have approximation arguments to justify such a choice. Indeed, since $v_h = \text{const}$ on $E_i$, the equation

$$
\int_{\Omega} (\text{div} p_h + f) v_h \, dx = 0 \quad \forall v_h \in V_h.
$$

is equivalent to

$$
\int_{\Omega} (\text{div} p_h + [f]_E) v_h \, dx = 0 \quad \forall v_h \in V_h.
$$

where $[f]_E$ is the function taking mean values of $f$ on each cell.
Thus, in this lowest order approximations, the variability of $f$ inside a cell is ignored and in reality we use the relation

$$\text{div} p + [f]_E = 0.$$ 

Therefore, for the flux approximation it is natural to impose the condition:

$$\text{div} p_h = \text{const} \quad \text{on} \ E^i$$
Certainly, \( P_n \) must additionally satisfy the natural condition on that the norm \( \|Q_n\|_n \) must be equivalent to the norm of the vector \( q(n) \). This leads to certain requirements on the structure of the mesh, which are satisfied under the assumptions we have imposed on \( \mathcal{T}_h \).

Having \( P_{n_s} \) for each cell \( n_s \), we define the *global extension operator*

\[
P_\Omega : q(\mathcal{T}_h) \rightarrow Q_h
\]

by setting

\[
P_\Omega q(x) = P_{n_s} q(n_s)(x), \quad \text{if } x \in n_s
\]

for any \( q \in q(\mathcal{T}_h) \).
Consider the respective saddle point problem for the Lagrangian

\[ L(v_h, q_h) = - \int_\Omega \left( v_h \text{div} q_h + \frac{1}{2} |q_h|^2 + f v_h \right) \, dx \]

on \( V_h \times Q_h \). Components of the saddle point \((u_h, p_h)\) are solutions of two variational problems associated with the Lagrangian \( L \). The first problem \( \mathcal{P}_h \) is to find \( u_h \in V_h(\Omega) \) such that

\[ \inf_{v_h \in V_h(\Omega)} J_h(v_h) = J_h(u_h) := \inf \mathcal{P}_h, \]

where

\[ J_h(v_h) = \sup_{q_h \in Q_h} L(v_h, q_h). \]
Another (dual) problem $\mathcal{P}_h^*$ is to find $p_h$ that maximizes the functional

$$I(q_h) = -\frac{1}{2} \int_{\Omega} |q_h|^2 \, dx$$

on the set

$$Q_{fh}(\Omega) := \left\{ q_h \in Q_h \mid \int_{\Omega} (\text{div}q_h + f)v_h \, dx = 0 \ \forall v_h \in V_h \right\}.$$
Well–posedness of the discrete problems

Under the above made assumptions on the external data and \( \mathcal{F}_h \) both these problems \( P_h \) and \( P_h^* \) are stable and well–posed.

**Assumption.** For any \( v_h \in V_h(\Omega) \) one can find a function \( \eta_h \in Q_h(\Omega) \) such that

\[
\text{div}\eta_h|_{n_s} = v_h|_{n_s}, \quad s = 1, 2, \ldots N
\]

(181)

\[
\|\eta_h\|_{H(\Omega,\text{div})} \leq C\|v_h\|_{\Omega},
\]

(182)

where the constant \( C \) depends on \( \Omega \).

**Proposition 1.** Functional \( J_h \) is coercive on \( V_h \).
Proof

Let $v_h \in V_h$. For any $v_h$, we find $\eta_h$ in accordance with conditions of Proposition 1. For any positive $\alpha$

$$J_h(v_h) = \sup_{q_h \in Q_h} L(v_h, q_h) \geq \int_{\Omega} \left( \alpha v_h \text{div} \eta_h - \frac{\alpha^2}{2} |\eta_h|^2 - f v_h \right) dx.$$  

By (181) and (182), we obtain

$$J_h(v_h) \geq \sum_{s=1}^{N} \alpha \|v_h\|_{\Pi_s}^2 - \frac{\alpha^2 C^2}{2} \|v_h\|_{\Omega}^2 - \int_{\Omega} f v_h dx =$$

$$= \alpha \left( 1 - \frac{\alpha C^2}{2} \right) \|v_h\|_{\Omega}^2 - \int_{\Omega} f v_h dx.$$
Take $\alpha = \frac{1}{C^2}$. Then

\[
J_h(v_h) \geq \frac{1}{2C^2} \|v_h\|^2_\Omega - \int_\Omega f v_h \, dx \geq \frac{1}{4C^2} \|v_h\|^2_\Omega - C^2 \|f\|^2_\Omega
\]

(183)

and the coercivity of $J_h$ on $V_h$ follows.
Proposition 2. $J_h$ is convex and lower semicontinuous on $V_h$.

Corollary. Since the functional $J$ is convex, lower semicontinuous and coercive on $V_h$, known theorems of the calculus of variations guarantee that the minimizer $u_h$ exists (see, e.g., [?]). Moreover, from (183) it follows that

$$\frac{1}{4C^2} \|u_h\|^2_{\Omega} \leq C^2 \|f\|^2_{\Omega} + J_h(v_h) \quad \forall v_h \in V_h. \quad (184)$$

For any partition $\mathcal{T}_h$ the zero function belongs to $V_h$ and $J_h(0) = 0$. Therefore, the second term in the right–hand side of (184) vanishes and we see that the norm of $u_h$ is uniformly bounded with respect to $h$. This means that the problems $P_h$ are stable.
It is also not difficult to justify the well-posedness of the dual problem. Indeed, Problem $\mathcal{P}_h^*$ is a problem of maximization a quadratic functional on the affine set $Q_{fh}$, which has a unique solution provided that this set is not empty.
Since
\[
\int_{\Omega} (\text{div} \, p_h + f) w_h \, dx = 0 \quad \forall w_h \in V_h(\Omega), \tag{185}
\]
\[
\int_{\Omega} (p_h \cdot q_h + u_h \text{div} q_h) \, dx = 0 \quad \forall q_h \in Q_h(\Omega), \tag{186}
\]
we arrive at the conclusion that
\[
\|p_h\|_\Omega^2 = \int_{\Omega} f u_h \, dx \leq \|f\|_\Omega \|u_h\|_\Omega.
\]
In view of (184), we obtain

\[ \| p_h \|_\Omega^2 \leq 2C^2 \| f \|_\Omega^2. \]  

(187)

It is worth noting that elements of \( Q_{fh}(\Omega) \) satisfy the condition

\[ - (\text{div} \, q_h)_{n_s} = \frac{1}{|n_s|} \int_{n_s} f \, dx. \]

Really, is set \( w_h = 0 \) on all the cells except \( n_i \) and \( w_h = c \) on that single sell. then

\[ \int_\Omega (\text{div} \, q_h + f) \, c \, dx = 0 \Rightarrow [\text{div} \, q_h + f]_{n_i} = 0, \]

i.e.,

\[ (\text{div} \, q_h)_{n_s} |_{n_s} + \int_{n_s} f \, dx = 0 \]
Since $p_h \in Q_{fh}(\Omega)$, we see that

\[
(div\, p_h)_n = -\frac{1}{|n_s|} \int_{n_s} f dx = \frac{1}{|n_s|} \int_{n_s} \text{div} p.
\]  

Thus, $\text{div} p_h$ is the cell–averaging of $\text{div} p$.  

(188)
From (187) and (188) it follows that

\[ \| p_h \|_{\text{div}, \Omega} \leq \text{const}. \]

Moreover, by (188) and the property of averaged functions we conclude that if \( f \) is a smooth (or piecewise smooth) function then \( \text{div} p_h \to \text{div} p \) a.e. in \( \Omega \).

If \( f \in W_2^1(\Omega) \), then from the Poincaré inequality for the functions with zero mean we also find that

\[ \| \text{div} p_h - \text{div} p \|_{\Omega} \to 0 \text{ as } h \to 0. \]
Other results on the convergence of $u_h$ to $u$ and $p_h$ to $p$ follow from the above stability estimates provided that the spaces $V_h$ and $Q_h$ are limit dense in $V$ and $Q$, respectively: for any $V \in V$ (resp. $q \in Q$) and any positive $\varepsilon$ one can find $h_\varepsilon$ such that for $h \leq h_\varepsilon$ $V_h$ contains a function $V_\varepsilon$ satisfying the relation $\|v - v_\varepsilon\|_\Omega \leq \varepsilon$ (resp. $Q_h$ contains $q_\varepsilon$ satisfying the relation $\|q - q_\varepsilon\|_{\text{div},\Omega} \leq \varepsilon$).

Then, for any $w \in V$ and $q \in Q$ there exist sequences $\{w_h\} \in V_h$ and $\{q_h\} \in Q_h$ that strongly converge to $vw$ and $q$ in $V$ and $Q$, respectively.
Since the sequences \( \{u_h\} \) and \( \{p_h\} \) are uniformly bounded, they contain subsequences weakly converging to some limits \( \tilde{u} \in V \) and \( \tilde{q} \in Q \), respectively. Passing to the limit in (185)–(186) we obtain

\[
\int_{\Omega} (\text{div}\tilde{p} + f) w \, dx = 0 \quad \forall w \in V(\Omega), \tag{189}
\]

\[
\int_{\Omega} (\tilde{p} \cdot q + \tilde{u}\text{div}q) \, dx = 0 \quad \forall q \in Q(\Omega), \tag{190}
\]

what means that \( \tilde{u} = u \) and \( \tilde{p} = p \), i.e. the sequences converge to the solution of the basic problem.
Take sequences $\hat{u}_h \to u$ in $V$ and $\hat{p}_h \to p$ in $Q$. We have

$$L(u_h, q_h) \leq L(u_h, p_h) \leq L(v_h, p_h) \quad \forall v_h \in V_h, \; q_h \in Q_h. \quad (191)$$

Therefore,

$$J_h(u_h) = \sup_{q_h \in Q_h} L(u_h, q_h) = L(u_h, p_h), \quad (192)$$

$$I(p_h) = \inf_{v_h \in V_h} L(v_h, p_h) = L(u_h, p_h) \quad (193)$$

and

$$\lim_{h \to 0} I(p_h) \geq \lim_{h \to 0} L(\hat{p}_h, u_h) = \lim_{h \to 0} \int_{\Omega} \left( u_h \text{div} \hat{p}_h - \frac{1}{2} |\hat{p}_h|^2 - fu_h \right) dx = L(u, p) = I(p). \quad (194)$$
Since \( \mathbf{p}_h \) weakly converges to \( \mathbf{p} \), we have

\[
\lim_{h \to 0} \| \mathbf{p}_h \|_{\Omega} \geq \| \mathbf{p} \|_{\Omega},
\]

what gives the relation

\[
\lim_{h \to 0} I(\mathbf{p}_h) \leq I(\mathbf{p}).
\] (195)

From (194) and (195) we conclude that

\[
\lim_{h \to 0} I(\mathbf{p}_h) = I(\mathbf{p}).
\] (196)

Thus, \( \| \mathbf{p}_h \|_{\Omega} \to \| \mathbf{p} \|_{\Omega} \) and, consequently, \( \| \mathbf{p}_h - \mathbf{p} \|_{\Omega} \to 0 \).
Examples of extension operators

Quadrilateral cells in $\mathbb{R}^2$.
Quadrilateral cell $\Pi$ with nodes numerated 1, 2, 3, and 4. Edges are denoted by $E_{12}$, $E_{23}$, $E_{34}$, and $E_{14}$. Below we construct a cell extension operator $\mathbb{P}_n$ valid for a convex, nonconvex and degenerate cells.
To construct an extended function $Q_n$, that satisfies the conditions $Q_n|_{E_{st}} \cdot \nu_{st} = q_{st}$ (where $\nu_{st}$ denotes the unit normal to $E_{st}$) we introduce a subsidiary edge $E_{13}$ and define the respective normal component $q_{13}$ from the condition

$$
\frac{1}{|T_{123}|} \int_{T_{123}} \text{div}(Q_n) dx = \frac{1}{|T_{134}|} \int_{T_{134}} \text{div}(Q_n) dx, (197)
$$

which means that the divergence of the extended function $Q_n$ is constant on $n$. 
From (197) we obtain

\[ q_{13} = \rho \left( \frac{q_{12} |E_{12}|}{|T_{123}| |E_{13}|} + \frac{q_{23} |E_{23}|}{|T_{123}| |E_{13}|} + \frac{q_{14} |E_{14}|}{|T_{134}| |E_{13}|} - \frac{q_{34} |E_{34}|}{|T_{134}| |E_{13}|} \right), \quad (198) \]

where

\[ \rho = \frac{|T_{123}| |T_{134}|}{|T_{123}| + |T_{134}|}. \]

Now, for each of the two triangles we can construct the field using the lowest order Raviart–Thomas elements. This field meets the conditions \( \text{div} Q_n = \text{const} \) in \( n \) and

\[ \int_n \text{div} Q_n \, dx = q_{12} |E_{12}| + q_{23} |E_{23}| + q_{34} |E_{34}| + q_{14} |E_{14}|. \quad (199) \]
It is possible to show that the extension operator satisfies the relation

$$\| Q_n \|_{\bar{n}}^2 \leq h^2 \mu_2(n) \sum_{E_{st} \in \partial n} q_{st}^2,$$

where $\mu_2$ is a positive constant depending on the shape of a cell $n$. For this purpose, at each node, we define vectors associated with certain triangle containing this node. It means that it is bounded.
Polygonal cells in $\mathbb{R}^3$

Figure: Extension inside a prism
Denote the normal components of the flux on the faces $E_{1245}$, $E_{2356}$, $E_{1346}$, $E_{123}$, and $E_{456}$ by $q_1$, $q_2$, $q_3$, $q_4$, and $q_5$, respectively. Introduce two subsidiary internal faces $E_{234}$ and $E_{345}$ with normal components $q'$ and $q''$ oriented inside $n$. Now, the prism is divided into 3 tetrahedrons $T_{1234}$, $T_{2345}$, and $T_{3456}$. The divergence of the extended field is defined via the Stokes theorem as

$$\text{div} P_n = g_n,$$

where

$$g_n = q_1|E_{1245}| + q_2|E_{2356}| + q_3|E_{1346}| + q_4|E_{123}| + q_5|E_{456}|.$$
Since the condition $\text{div} \mathbb{P}_n = g_n$ must hold on each of the tetrahedrons, we obtain

\[ q_1 |E_{124}| + q' |E_{234}| + q_3 |E_{134}| + q_4 |E_{123}| = g_n |T_{1234}|, \]
\[ q_2 |E_{356}| + q'' |E_{345}| + q_3 |E_{346}| + q_5 |E_{456}| = g_n |T_{3456}|. \]

Thus, the numbers $q'$ and $q''$ and the respective extension $\mathcal{Q}_n$ are uniquely defined.
General method of constructing $\mathbb{P}_n$

In more complicated cases as, e.g., for

$$\text{internal fluxes are easily excluded by the } \text{div} q_h = \text{const} \text{ condition and the Stokes theorem.}$$
In fact, we have constructed an interpolation operator $\pi^Q$ on each cell. If $q$ is a vector-valued function defined on $E^i$ having summable traces, then the normal flux on $e_{ij} \subset \partial E^i$ can be defined as follows

$$q^{ij} = \frac{1}{|e_{ij}|} \int_{e_{ij}} q \cdot \nu_{ij} ds$$

By extending the field inside $E^i$ we obtain the function $q_h$ such that

$$q_h \in H(\Omega, \text{div}), \quad \text{div}q_h = \text{const} \text{ on } E^i$$
$$q_h \text{ is piecewise affine in } E^i$$

and, thus, define the interpolation operator

$$\pi^Q : Q \rightarrow Q_h.$$
A cell with internal nodes
For such a sell there are many different fields that satisfy the condition

$$\text{div} q_h = \text{const}. $$

To avoid nonuniqueness the condition

$$\|q_h\|_{E_i} \rightarrow \min$$

should be used.
We may *equivalently formulate additional condition* as follows. Using the lowest order Raviart–Thomas finite elements we find ”local” $Q_\pi$ satisfying the boundary condition $Q_\pi \cdot \nu = q(\pi) \cdot \nu$ as a solution of the discrete problem

\begin{align*}
\int_\pi (v_\tau \text{div} Q_\pi + g_\pi v_\tau) \, dx &= 0 \quad \forall v_\tau \in V_\tau, \tag{201} \\
\int_\pi (Q_\pi \cdot q_\tau + u_\tau \text{div} q_\tau) \, dx &= 0 \quad \forall q_\tau \in Q_{0\tau}, \tag{202}
\end{align*}

where $V_\tau$ is the space of piecewise constant functions and $Q_{0\tau}$ is the finite element space formed by Raviart–Thomas elements contained in $H(\Omega, \text{div})$ and subject to the boundary condition

$$q_\tau \cdot \nu = 0 \quad \text{on} \ \partial \pi.$$
It is well known that this problem has a unique solution $Q_\Pi$ and the function $u_\tau$ is uniquely defined up to an arbitrary constant. In virtue of (201),
\[
\mathrm{div} Q_\Pi + g_\Pi = 0 \quad \text{in} \, \Pi,
\] (203)
so that the requirement $\mathrm{div} Q_\Pi = \text{const}$ is satisfied. Since $Q_\Pi \in H(\Pi, \mathrm{div})$, the condition (180c) is also satisfied.
Note that the function $Q_n$ can be also viewed as a solution of the respective discrete problem with Neumann boundary conditions, which is to maximize the functional

$$I_n(q_\tau) = -\frac{1}{2} \int_{\Omega} |q_\tau|^2 dx$$

on the set of fields satisfying the condition

$$\text{div} q_\tau = g_\Pi$$

and the prescribed boundary conditions. If $\Pi$ is divided into a few subdomains (as, e.g., in the above example for quadrilaterals), then such a condition may uniquely define the field. However, in other cases fields with constant divergence may create a subspace. In this case, uniqueness of the extension is provided by the fact that the minimizer of the quadratic functional $I_n$ on this subspace is uniquely defined.
Rate convergence estimates. General line

We analyze 3 different mixed approximations on distorted meshes:
A. The finest approximation on the mesh $\tilde{T}_h$ when all cells are decomposed into simplexes. On simplexes the pressure field is assumed to be constant and the flux is approximated by the $RT^0$ elements. This gives the pair of spaces $(\tilde{V}_h, \tilde{Q}_h)$.
B. The approximation on the mesh $T_h$ that consists of all cells. On cells the pressure field is assumed to be constant and the flux is approximated by the procedure discussed further. This gives the pair of spaces $(V_h, Q_h)$.
C. $T_h$ is the same, but normal fluxes are averaged on each ”macroface” $e$. This gives the pair of spaces $(V^e_h, Q^e_h)$. 
"Referenced" problem

Consider the dual mixed formulations on $\tilde{T}_h$:

Problem $\tilde{P}_h$: find $(\tilde{p}_h, \tilde{u}_h) \in \tilde{Q}_h \times \tilde{V}_h$ such that

$$\int_{\Omega} (\tilde{p}_h \cdot \tilde{q}_h + \tilde{u}_h \text{div} \tilde{q}_h) dx = 0 \quad \forall \tilde{q}_h \in \tilde{Q}_h$$

$$\int_{\Omega} (\text{div} \tilde{p}_h + f) \tilde{v}_h dx = 0 \quad \forall \tilde{v}_h \in \tilde{V}_h.$$
Problem $\tilde{P}_h$ is used as the ”referenced” one. Its properties are known (see, e.g., F. Brezzi, M. Fortin, J.E. Roberts and J.-M. Thomas, 1991.)

1. If $\tilde{\mathcal{T}}_h$ is regular then the inf-sup condition

$$\inf_{\tilde{\mathcal{V}}_h} \sup_{\tilde{\mathcal{Q}}_h} \frac{\int_{\Omega} \tilde{v}_h \text{div} \tilde{q}_h \, dx}{\|\tilde{v}_h\| \|\tilde{q}_h\|_{\text{div}, \Omega}} \geq \tilde{C}$$

holds with a constant $C$ independent of $h$. 

2. Problem $\tilde{\mathcal{P}}_h$ is uniquely solvable for any $h > 0$ and
\[
\tilde{u}_h \to u \text{ in } V(\Omega), \quad \tilde{p}_h \to p \text{ in } Q.
\]
Moreover, for the $RT^0$ approximations we have the standard rate convergence estimate
\[
\|\tilde{p}_h - p\|_{\text{div}, \Omega} + \|\tilde{u}_h - u\| \leq C_{RT} h (|u|_{1, \Omega} + \|p\|_{1, \Omega} + \|\text{div} p\|_{1, \Omega})
\]
that holds provided that the exact solution is sufficiently regular.
We use the above properties of Problem $\tilde{P}_h$ in order to establish similar properties for Problems $P_h$ and $P^e_h$. 
First dual mixed formulations on $\mathcal{T}_h$

Problem $\mathcal{P}_h$: find $(p_h, u_h) \in Q_h \times V_h$ such that

$$\int_{\Omega} (p_h \cdot q_h + u_h \text{div} q_h) \, dx = 0 \quad \forall q_h \in Q_h$$  \hspace{1cm} (205)$$

$$\int_{\Omega} (\text{div} p_h + f) v_h \, dx = 0 \quad \forall v_h \in V_h. \quad \hspace{1cm} (206)$$

$$V_h := \{ v_h \in V = L^2(\Omega) \mid v_h \in P^0(\mathcal{E}^i), \ i = 1, 2, \ldots N \},$$

$$Q_h := \{ q_h \in Q_h \mid \text{div} q_h \in P^0(\mathcal{E}^i), \ i = 1, 2, \ldots N \}.$$

Mathematical properties of this problem are in focus of the investigation.
Reduced space $Q^e_h$

In real life problems, analysts are often faced with meshes having "nonmatching" faces.

Certain faces of a cell may belong to one common plane and create a common boundary of one cell (macroface) denoted by $\Gamma_h$. We can reduce degrees of freedom on a macroface if replace different normal fluxes given on $e$ by one on the basis of the condition: the value of $\int_e q_h \cdot \nu$ remains unchanged.
By this "averaging" procedure we replace \( \mathbf{q}_h \) by \( \mathbf{q}_h^e \in \mathbf{Q}_h^e \) and obtain a new space for fluxes:

\[
\mathbf{Q}_h^e := \{ \mathbf{q}_h \in \mathbf{Q}_h \mid \mathbf{q}_h \cdot \nu = \text{const} \quad \forall e \in \Gamma_h \}
\]
Second dual mixed formulations on $\mathcal{T}_h$

Problem $\mathcal{P}_h^e$ Find $(p_h^e, u_h^e) \in Q_h^e \times V_h$ such that

$$\int_{\Omega} (p_h^e \cdot q_h^e + u_h^e \text{div} q_h^e) dx = 0 \quad \forall q_h^e \in Q_h^e,$$ \hspace{1cm} (207)

$$\int_{\Omega} (\text{div} p_h^e + f) v_h dx = 0 \quad \forall v_h \in V_h.$$ \hspace{1cm} (208)

It is clear that $V_h \subset \widetilde{V}_h \subset V$ and $Q_h^e \subset Q_h \subset \widetilde{Q} \subset Q$. 
Main goals

We show that if the above "aggregation–reduction" procedures are properly done and Problem $\tilde{P}_h$ is stable and convergent, then

(a) the inf–sup conditions for $(V_h, Q_h)$ and $(V_h, Q_h^e)$ are satisfied;

(b) $q_h$ and $q_h^e$ converges to $p$ in $Q$ with the same rate as $\tilde{q}_h$ and $v_h$ and $v_h^e$ converges to $u$ in $V$ with the same rate as $\tilde{v}_h$;

(c) computational errors for the approximations of all types can be explicitly controlled by the a posteriori estimates presented.
Assumptions

More precisely, we assume that

1. \( c_1 h \leq \text{diam} E^i \leq c_2 h, \quad \forall E^i \in \mathcal{T}_h, \)

2. Number of simplexes in a cell is from 1 to \( m_{\text{max}}. \)

3. \( \{\tilde{\mathcal{T}}_h\} \) is regular in the usual sense:
   - All angles of simplexes are uniformly bounded,
   - Any face of a simplex is either a part of a boundary or a face of another simplex

\[
\theta_1 h^d \leq |T^i_j| \leq \theta_2 h^d, \quad \forall T^i_j \in \tilde{T}_h
\]

If \( e \) is a face of \( T^i_j \) then

\[
\gamma_1 h^{d-1} \leq |e| \leq \gamma_2 h^{d-1}.
\]
Logical scheme

1. Inf Sup in $\tilde{\mathcal{P}}_h \Rightarrow$ Inf Sup in $\mathcal{P}_h \Rightarrow$ Inf Sup in $\mathcal{P}^e_h$

2. Construct interpolation operators

$$\pi^Q : Q \rightarrow Q_h \text{ and } \pi^V : V \rightarrow V_h$$

3. Establish projection type estimates

4. Obtain estimates for $\|\tilde{\pi}^Q p - \pi^Q p\|$ and $\|\tilde{\pi}^V p - \pi^V p\|$
First, we prove that for the cell-approximations Inf-Sup condition holds:

**Proposition**

Let \( \{ \tilde{T}_h \} \) satisfies the above made assumptions. Then, for any \( \mathbf{v}_h \in \mathbf{V}_h \) there exists a vector-valued function \( \mathbf{\eta}_h \in \mathbf{Q}_h \) such that

\[
-\text{div}\mathbf{\eta}_h = \mathbf{v}_h \quad \text{on each } E^i
\]

\[
\|\mathbf{\eta}_h\|_{\text{div},\Omega} \leq C\|\mathbf{v}_h\|,
\]

where \( C \) does not depend on \( h \) and \( \mathbf{V}_h \).
Proof.

Set $\mathbf{f} = v_h$. Let $(\tilde{\mathbf{p}}^v, \tilde{\mathbf{u}}^v) \in \tilde{Q}_h \times \tilde{V}_h$ be the pair of functions that satisfies the system

$$
\int_{\Omega} (\tilde{\mathbf{p}}^v \cdot q_h + \tilde{\mathbf{u}}^v \text{div} q_h) dx = 0 \quad \forall q_h \in \tilde{Q}_h \tag{211}
$$

$$
\int_{\Omega} (\text{div} \tilde{\mathbf{p}}^v + v_h) v_h dx = 0 \quad \forall v_h \in \tilde{V}_h. \tag{212}
$$

We observe that

$$
-\text{div} \tilde{\mathbf{p}}^v = v_h \quad \text{on any } T^i_j.
$$
Since \( v_h \) is constant on \( E^i \), we arrive at the conclusion that
\[ -\text{div} \tilde{p}^\nu_h = v_h \quad \text{on any } E^i. \]

Now we construct the required \( \eta^\nu_h \) by means of \( \tilde{p}^\nu_h \) as follows. On each cell we set normal components of \( \eta^\nu_i \) equal to the normal components of \( \tilde{p}^\nu_i \). If \( E^i \) contains no internal points, then (265) uniquely defines \( \eta^\nu_h \) by the values of normal fluxes on \( \partial E^i \). Thus, in this case, we simply set \( \eta^\nu_h = \tilde{p}^\nu_h \) in the cells.
If $E^i$ has an internal point, then $\eta^\nu_h$ is defined in accordance with *minimal energy principle*, i.e.,

$$
\|\eta^\nu_h\|_{E^i}^2 = \inf_{\tau^h \in \mathcal{N}(E^i)} \|\tau^h\|_{E^i}^2.
$$

(213)

Since $\tilde{p}^\nu_h \in \mathcal{N}(E^i)$ and $\text{div}\tilde{p}^\nu_h + \nu_h = 0$ we observe that

$$
\|\eta^\nu_h\| \leq \|\tilde{p}^\nu_h\|.
$$

(214)
Set $\tilde{q}_h = \tilde{p}_h^v$ in (268). Then,
\[
\|\tilde{p}_h^v\|^2 \leq \|\tilde{u}_h^v\|\|\text{div} \tilde{p}_h^v\| = \|\tilde{u}_h^v\|\|\tilde{v}_h\|.
\]

By assumption Inf–Sup condition for $\tilde{Q}_h \times \tilde{V}_h$ holds! Therefore, for the function $\tilde{u}_h^v$ we can find a vector–valued function $\tilde{q}_h^u \in \tilde{Q}_h$ such that
\[
\int_{\Omega} \tilde{u}_h^v \text{div} \tilde{q}_h^u \, dx \geq \tilde{C}\|\tilde{u}_h^v\|\|\tilde{q}_h^u\|
\]

Since
\[
\int_{\Omega} (\tilde{p}_h^v \cdot \tilde{q}_h^u + \tilde{u}_h^v \text{div} \tilde{q}_h^u) \, dx = 0
\]

we observe that
\[
\tilde{C}\|\tilde{u}_h^v\|\|\tilde{q}_h^u\| \leq - \int_{\Omega} \tilde{p}_h^v \cdot \tilde{q}_h^u \, dx \leq \|\tilde{p}_h^v\|\|\tilde{q}_h^u\|
Therefore,

\[ \| \tilde{u}_h^\nu \| \leq \frac{1}{C} \| \tilde{p}_h^\nu \|. \]

Now, (215) leads to the estimate

\[ \| \tilde{p}_h^\nu \| \leq \frac{1}{C} \| v_h \|. \] (216)

Since \( \eta_h^\nu = \tilde{p}_h^\nu \), we have

\[ \| \eta_h^\nu \|_{\text{div}, \Omega}^2 \leq \left( 1 + \frac{1}{C^2} \right) \| v_h \|^2. \]
**Corollary 1.** It is easy to see that under the conditions of Proposition 1, the discrete inf-sup condition for the spaces \((Q_h, V_h)\) holds. Indeed, take arbitrary \(v_h \in V_h\). We have

\[
\sup_{q_h \in Q_h} \frac{\int_{\Omega} v_h \text{div} q_h \, dx}{\|v_h\| \|q_h\|_{\text{div}, \Omega}} \geq \frac{\int_{\Omega} v_h \text{div} \eta_h^\vee \, dx}{\|v_h\| \|\eta_h^\vee\|_{\text{div}, \Omega}} \frac{\|v_h\|_{\text{div}, \Omega}}{\|\eta_h^\vee\|_{\text{div}, \Omega}} = C.
\]

Thus, for \((V_h, Q_h)\) the inf-sup condition holds with a certain positive constant \(C\) depending on \(\tilde{C}\).
If for cell–approximations Inf–Sup holds, then for them PROJECTION ESTIMATE HOLDS

\[ \| p - p_h \|_{\text{div}, \Omega} + \| u - u_h \| \leq \]

\[ \leq C \left\{ \inf_{q_h \in Q_h} \| p - q_h \|_{\text{div}, \Omega} + \inf_{w_h \in V_h} \| u - w_h \| \right\} . \]
Key point in deriving a priori estimates

In projection estimates we have quantities of the type

$$\inf_{q_h \in Q_h} \| p - q_h \|, \quad \inf_{v_h \in V_h} \| u - v_h \|.$$ 

We estimate them by

$$\| p - \pi^Q p \| \leq \| p - \tilde{\pi}^Q p \| + \| \tilde{\pi}^Q p - \pi^Q p \|,$$

$$\| u - \pi^V u \| \leq \| u - \tilde{\pi}^V u \| + \| \tilde{\pi}^V u - \pi^V u \|$$

For $RT^0$ approximations on $\tilde{T}_h$ we have the estimate

$$\| p - \tilde{\pi}^Q p \| \sim h, \quad \| u - \tilde{\pi}^Q u \| \sim h.$$
Therefore, we need to estimate the difference between interpolation operators on the "fine" and "coarse" meshes.

**Estimates for "pressure" interpolants.**

\[
\| \pi_h^V w - \tilde{\pi}_h^V w \| \leq C_V E(T_h, \tilde{T}_h, w),
\]

(217)

where the constant \( C_V \) does not depend on \( h \) and the quantity \( E \) is defined by the relations

\[
E(T_h, \tilde{T}_h, w) = \max_{i=1,2,...N} E_i(w),
\]

\[
E_i(w) = \max_{j=1,...,m_i} \left| [w]_{T_i}^j - [w]_{E_i}^j \right|.
\]
Indeed, take a cell $E^i$ and a simplex in it.

\[
\int_{T_j} (\pi_h \nu w - \tilde{\pi}_h \nu w)^2 \, dx = |T_j^i| \left( \frac{1}{|E^i|} \int_{E^i} w \, dx - \frac{1}{|T_j^i|} \int_{T_j^i} w \, dx \right)^2 =
\]

\[
= |T_j^i| \left( \frac{|T_j^i| \int_{E^i} w \, dx - |E^i| \int_{T_j^i} w \, dx}{|E^i||T_j^i|} \right)^2 =
\]

\[
= |T_j^i| \left( \frac{|T_j^i| \int_{E^i \setminus T_j^i} w \, dx - |E^i \setminus T_j^i| \int_{T_j^i} w \, dx}{|E^i||T_j^i|} \right)^2 =
\]

\[
= \frac{|T_j^i||E^i \setminus T_j^i|^2}{|E^i|^2} \left( [w]_{E^i \setminus T_j^i} - [w]_{T_j^i} \right)^2 .
\]
Now, we apply the estimate

\[
\left(\left[ w \right]_{E_i \setminus T_j} - \left[ w \right]_{T_j} \right)^2 \leq 2 \left[ \left(\left[ w \right]_{E_i \setminus T_j} - \left[ w \right]_{E_i} \right)^2 + \left(\left[ w \right]_{T_j} - \left[ w \right]_{E_i} \right)^2 \right]
\]

and note that

\[
\left[ w \right]_{E_i \setminus T_j} - \left[ w \right]_{E_i} \leq E_i(w).
\]

By these arguments we obtain

\[
\int_{T_j} (\pi_h^V w - \tilde{\pi}_h^V w)^2 \, dx \leq 2 |T_j| \mu_i^2 E_i^2(w).
\]

By summing over all simplexes, than over all cells we obtain (279). Since \( \mu_i \leq 1 \), \( C_V = 2 \).
Similar estimate holds true for the interpolants of fluxes

$$
\| \pi_h^Q q - \widetilde{\pi}_h^Q q \|_{\text{div}, \Omega} \leq \bar{\sigma} E(\Xi_h, \widetilde{\tau}_h, \text{div} q),
$$

(218)
Rate convergence estimates for \( p_h \) and \( u_h \)

By the above results we arrive at \textit{a priori rate convergence estimates} for approximations on distorted meshes (see Yu. Kuznetsov and S. Repin, JNM, 2005).

\[
\|p - p_h\|_{\text{div}, \Omega} + \|u - u_h\| \leq C \left[ h \left( \|p\|_{1, \Omega} + \|\text{div} p\|_{1, \Omega} + \|\nabla u\| \right) + E(T_h, \tilde{T}_h, \text{div} p) + E(T_h, \tilde{T}_h, u) \right],
\]
A posteriori estimates for cell approximations

\[ \| p - p_h \| \leq \sqrt{2} \| \nabla u_h - \hat{p}_h \| + 2C_\Omega \| \text{div} p_h + f \|, \]

Since \(-\text{div} p_h = [f]_E\), we can rewrite this upper bound as

\[ \| p - p_h \| \leq \sqrt{2} \| \nabla u_h - \hat{p}_h \| + 2C_\Omega \| [f]_E - f \|, \]
A POSTERIORI ESTIMATES FOR PROBLEMS IN THE THEORY OF VISCOUS INCOMPRESSIBLE FLUIDS
Lecture plan

- Mathematical models of viscous fluids;
- Stokes problem;
- Inf-sup condition;
- A posteriori estimates for solenoidal approximations;
- A posteriori estimates for non-solenoidal approximations;
- A posteriori estimates for problems with condition \( \text{div} v = \phi \);
- A posteriori estimates for problems on a subspace.
- Bingham fluids. A posteriori estimates.
Coordinates of particles at $t = 0$ are denoted $X$ and called Lagrangian coordinates. They serve as particles labels. Then, the trajectory of an individual particle is given by the relation

$$x = x(X, t),$$

where $x$ denote the Cartesian coordinates of particles at the moment $t$. They are called Euler coordinates.

Motion equations describing evolution of a media have the form

$$\rho_0 \frac{\partial v}{\partial t} (x, t) + v_i (x, t) \frac{\partial v}{\partial x_i} (x, t) = \text{div} \ \sigma (x, t) + f (x, t)$$

(219)
Here $\sigma$ is the effective stress, $\mathbf{v}_i \frac{\partial \mathbf{v}}{\partial x_i}$ is the so-called **convective term** which is often presented as

$$ (\mathbf{v} \cdot \nabla) \mathbf{v} (\mathbf{x}, t) $$

and

$$ \varepsilon (\mathbf{v}) = \frac{1}{2} (\mathbf{v}_{i,j} + \mathbf{v}_{j,i}) $$

(220)

is the tensor of small strains.

In the majority of models liquids are assumed to be **incompressible**, what means that

$$ \text{div} \mathbf{v} = 0. $$

In view of this fact

$$ \varepsilon (\mathbf{v}) = \varepsilon^D (\mathbf{v}). $$
Constitutive relation are usually given in the form

\[ \sigma = -pI + \tau, \tag{221} \]

where \( p \) is the pressure and \( I \) is the unit element of \( M_{s}^{n \times n} \) and ”deviatoric stress” is defined by the relation

\[ \tau \in \partial W (\varepsilon) \tag{222} \]

where \( W : M_{s}^{n \times n} \rightarrow \mathbb{R}_+ \) is the dissipative potential and \( \partial W \) stands for subdifferential.
Boundary conditions

Two main types of the problems:

**Flow of a fluid in a container (basin).**

\[ \Omega_0 = \Omega_t = \Omega, \quad t \geq 0; \quad \mathbf{v} = \mathbf{u}_0 \quad \partial \Omega \quad (223) \]

\[ \mathbf{v} = \mathbf{0} \text{ on } \partial \Omega \text{ is called the ”adhesion” or ”no–slip” condition.} \]

**Flow in an ”open” domain.**

In such a case, on a part of the boundary we set

\[ \sigma (\mathbf{x}, t) \mathbf{v} (\mathbf{x}, t) = \mathbf{F} (\mathbf{x}, t), \quad \mathbf{x} \in \partial \Omega_t, \quad t \geq 0 \quad (224) \]

**Initial condition.**

\[ \mathbf{v} (\mathbf{x}, 0) = \varphi (\mathbf{x}) \quad \mathbf{x} \in \Omega_0 \quad (225) \]
Now the task is to find $v$, $p$ $\tau$ such that

$$\rho_0 \frac{\partial v}{\partial t} + v_i \frac{\partial v}{\partial x_i} - \text{div} \, \sigma = f$$ \hfill (226)

$$\text{div} \, v = 0 \quad (x, t) \in Q := \Omega \times (0, +\infty)$$ \hfill (227)

$$\sigma = -pI + \tau, \quad \tau \in \partial W(\varepsilon)$$ \hfill (228)

$$v(x, t) = 0 \quad (x, t) \in \partial_1 \Omega \times (0, +\infty)$$ \hfill (229)

$$\sigma \nu = F \quad (x, t) \in \partial_2 \Omega \times (0, +\infty)$$ \hfill (230)

$$v(x, 0) = \varphi(x) \quad x \in \Omega$$
Bingham type fluids

\[
W(\varepsilon) = \frac{\mu}{m} |\varepsilon|^m + k_* |\varepsilon| 
\]

A particular case with \( k_* = 0 \) and \( m = 2 \) leads to

\[
\sigma = -p \mathbb{I} + \frac{\partial W}{\partial \varepsilon} = -p \mathbb{I} + \mu \varepsilon,
\]

Then

\[
\text{div } \sigma = -\nabla p + \mu \Delta v
\]

and we arrive at the Navier–Stokes system

\[
\begin{cases}
\rho_0 \frac{\partial v}{\partial t} + v_i \frac{\partial v}{\partial x_i} - \mu \Delta v = f + \nabla p \\
\text{div } v = 0
\end{cases}
\]

If \( k_* > 0 \) then it is typical that the stagnant zones with \( \varepsilon(v) \equiv 0 \) arise.
Power law models

\[ W(\varepsilon) = \mu_\infty |\varepsilon|^2 + \mu_0 \left( 1 + |\varepsilon|^2 \right)^{\frac{p}{2}} \]  \hspace{4cm} (233)

\[ W(\varepsilon) = \mu_\infty |\varepsilon|^2 + \mu_0 |\varepsilon|^p \] \hspace{4cm} (234)

Here \( p \in ]1, +\infty[ \), \( \mu_\infty \geq 0 \), \( \mu_0 \geq 0 \), \( \mu_\infty \mu_0 \neq 0 \).

Powel–Euring models

\[ W(\varepsilon) = \mu_\infty |\varepsilon|^2 + \mu_1 |\varepsilon| \ln (1 + |\varepsilon|) \] \hspace{4cm} (235)
In all the cases we have the system

\[
\begin{align*}
\rho_0 \frac{\partial v}{\partial t} + v_i \frac{\partial v}{\partial x_i} - \frac{\partial W}{\partial \varepsilon}(\varepsilon(v)) &= f + \nabla p \\
\text{div } v &= 0
\end{align*}
\]

(236)

In case of slow motions the term \( v \cdot (\nabla v) \) is usually neglected. Then, we arrive at simplified models among which the most known is the Stokes model.
Spaces of solenoidal functions

$$\dot{J}^\infty(\Omega) = \{ u \in C_0^\infty(\Omega), \text{div} u = 0, \text{supp} u \subset \Omega \},$$

$$\dot{J}(\Omega) := \text{closure of } \dot{J}^\infty \text{ in the topology of } L_2(\Omega, \mathbb{R}^d),$$

$$\dot{J}_2^1(\Omega)(\Omega) := \text{closure of } \dot{J}^\infty \text{ in the topology of } H^1(\Omega, \mathbb{R}^d).$$
Navier–Stokes equation

At present Navier–Stokes problem dominates among the models describing the behavior of viscous incompressible fluids. It is to find $u(x, t) \in \mathcal{H}^1_2(\Omega)$ and $p(x, t) \in \mathcal{L}^2(\Omega)$ such that

$$
\begin{align*}
    u_t - \nu \Delta u + \text{div}(u \otimes u) &= f - \nabla p \quad \text{in } \Omega, \\
    u(x, 0) &= \varphi(x), \\
    u &= u_0 \quad \text{on } \Gamma_D \\
    \varepsilon(u) \cdot \nu + p \nu &= g_N \quad \text{on } \Gamma_N.
\end{align*}
$$
From the mathematical point of view NS is still a mystery. Existence of a unique solution in 3D is not yet proved even for \((0, T] \times \mathbb{R}^n\).

It is known that for sufficiently regular solenoidal \(\phi(x)\) there exists a weak Leray-Hopf solution, i.e., a function

\[
\mathbf{u} \in L^\infty(0, T; L^2(\mathbb{R}^n)) \cap L^2(0, T; H^1(\mathbb{R}^n))
\]
Proving (or presenting a contr–example) of that NS equation possesses in 
$(0, T] \times \mathbb{R}^n$ a smooth solution provided that initial data are sufficiently 
regular forms one of the 
Millennium Prize Problems 
stated by the Clay Mathematical Institute.

From the introduction to the Third Millennium Prize Problem: 
"...Although these (NS) equations were written down in the 19th Century, 
our understanding of them remains minimal. The challenge is to make 
substantial progress toward a mathematical theory which will unlock the 
secrets hidden in the Navier-Stokes equations."
However, discrete (semidiscrete) analogs of NS equation are actively used in the Mathematical Modeling.

For example:

\[
\frac{u^k - u^{k-1}}{\Delta t} - \nu \Delta u^k + \text{div}(u^{k-1} \otimes u^{k-1}) = f - \nabla p^k \quad \text{in } \Omega,
\]

\[
\text{div} u^k = 0
\]

and

\[
\frac{u^k - u^{k-1}}{\Delta t} - \nu \Delta u^k + \text{div}(u^{k-1} \otimes u^k) = f - \nabla p^k \quad \text{in } \Omega,
\]

\[
\text{div} u^k = 0.
\]
For these reasons, an intensive investigations has been devoted to linearizations of NS equations, in particular to Stokes

\[ u_t - \nu \Delta u = f - \nabla p \quad \text{in } \Omega, \]
\[ u(x, 0) = \varphi(x), \]
\[ u = u_0 \quad \text{on } \Gamma_D \]
\[ \varepsilon(u) \cdot \nu + p \nu = g_N \quad \text{on } \Gamma_N \]

and Oseen

\[ u_t - \nu \Delta u + \text{div}(a \otimes u) = f - \nabla p \quad \text{in } \Omega, \]
\[ u(x, 0) = \varphi(x), \quad \text{div}a = 0, \]
\[ u = u_0 \quad \text{on } \Gamma_D \]
\[ \varepsilon(u) \cdot \nu + p \nu = g_N \quad \text{on } \Gamma_N \]

problems.
In certain cases (e.g., ocean modeling) NS equations should take into account Earth rotation. Then, an additional term arises and the equation comes in the form

$$u_t - \nu \Delta u + (u \cdot \nabla u) + \omega \times u = f - \nabla p \quad \text{in } \Omega,$$

where

$$\omega = |\omega|e_3.$$

is the parameter of the rotation intensity.
A significant part of the difficulties arising in the process of solving such problems is related to the **incompressibility condition** $\text{div} u = 0$. Typically, this condition is taken into account by projecting of a discrete solution to the set of solenoidal fields or by introducing appropriate penalty terms. A detailed exposition of the numerical methods can be found, e.g., in the works of (see the List of Literature) J. Chen, A. Chorin, W. E and J. G. Liu, M. Feistauer, M. Ganzburger, V. Girault, G. Heywood, R. Rannacher, P. A. Raviart, R. Temam. Stationary problems are often solved by passing to a minimax formulation and using the so–called mixed approximations for the velocity and pressure fields (see, e.g., F. Brezzi and J. Duglas, F. Brezzi and M. Fortin).
Linear models in the theory of fluids
Classical formulation of the Stokes problem: find a vector–valued function $u$ (velocity) and a scalar–valued function $p$ (pressure) that satisfy the relations

\begin{align*}
-\nu \Delta u &= f - \nabla p \quad \text{in } \Omega, \quad (237) \\
\text{div} u &= 0 \quad \text{in } \Omega, \quad (238) \\
u &= u_0 \quad \text{on } \partial \Omega, \quad (239)
\end{align*}

where $u_0$ is a given function such that $\text{div} u_0 = 0$. 
Here $\Delta$ denotes the Laplacian of a vector field:

$$\nabla^2 u = (\nabla^2 u_i) e_i,$$

$e_i$ are the cartesian unit vectors.

Multiply (237) by a function $v \in \mathcal{J}^\infty$. Then,

$$\int_{\Omega} \nabla p \cdot v \, dx = \int_{\Omega} p \, \text{div} v \, dx = 0,$$

and we arrive at the relation

$$\nu((u, v)) = (f, v) \quad \forall v \in \mathcal{J}^\infty(\Omega), \quad (240)$$

where $((u, v)) = \int_{\Omega} \varepsilon(u) : \varepsilon(v) \, dx$. Above identity can be extended by continuity to the whole $\mathcal{J}^{\frac{1}{2}}(\Omega)$. 
Weak formulation of the Stokes problem

Find \( u \in J^1_2(\Omega) \), such that \( u = 0 \) on \( \partial \Omega \) and

\[
\mu((u, v)) = (f, v) \quad \forall v \in J^1_2(\Omega)(\Omega),
\]

This formulation is related to the energy functional

\[
I(v) = \mu \int_\Omega |\nabla v|^2 \, dx - 2 \int_\Omega f v \, dx
\]

(241)

(242)

where \( |\nabla v|^2 = |\nabla v_1|^2 + \ldots + |\nabla v_n|^2 \).
Theorem

Generalized solution of the Stokes problem minimizes the functional \( I \) over \( \mathcal{H}^1_2(\Omega) \).

Proof. Assume that

\[
\mu((u, v)) = (f, v) \quad \forall v \in V.
\]

Since \( ||u - v||^2 \geq 0 \), we have

\[
\mu ||u||^2 + \mu ||v||^2 - 2\mu((u, v)) \geq 0.
\]  \( (243) \)

On the other hand,

\[
I(u) = \mu ||u||^2 - 2(f, u) = \mu ||u||^2 - 2\mu((u, u)) = -\mu ||u||^2
\]

Therefore, we rewrite (243) as follows:

\[
\mu ||v||^2 - 2\mu((u, v)) \geq I(u),
\]
Therefore,

\[ I(v) \geq I(u) \quad \forall v \in V. \quad (244) \]

Assume that \( u \) is the minimizer, then for any \( v \in V \)

\[
I(u + \lambda v) \geq I(u), \\
\mu \|u\|^2 + 2\lambda \mu((u, v)) + \mu \lambda^2 \|v\|^2 - 2(f, u + \lambda v) \geq \\
\geq \mu \|u\|^2 - 2(f, u),
\]

and, consequently,

\[
\mu((u, v)) - (f, v) \geq -\frac{\lambda}{2} \|v\|^2 \implies \mu((u, v)) - (f, v) = 0 \quad \forall v \in V.
\]
Next, \( W := W_2^1(\Omega, \mathbb{R}^d) \) and \( \Sigma := L_2(\Omega, \mathbb{M}^{d \times d}) \), where \( \mathbb{M}^{d \times d} \) is the space of symmetric \( d \times d \) matrixes (tensors), whose scalar product is denoted by two dots.

\( W_0 \) is a subspace of \( W \) that contains functions with zero traces on \( \partial \Omega \).

\( W_0 + u_0 \) contains functions of the form \( w + u_0 \), where \( w \in V_0 \).

Analogously, \( J_2^1(\Omega) + u_0 \) contains functions of the form \( w + u_0 \), \( w \in J_2^1(\Omega) \).

The operator \( \varepsilon(v) := \frac{1}{2}(\nabla v + (\nabla v)^T) \) acts from \( W \) to \( \Sigma \).
We will also use the Hilbert space $\Sigma_{\text{div}}(\Omega)$, which is a subspace of $\Sigma$ that contains tensor–valued functions $\tau$, such that $\text{div}\tau \in L_2$. The scalar product in this space is defined by the relation

$$ (\tau, \eta) := \int_{\Omega} (\tau : \eta + \text{div}\tau \cdot \text{div}\eta) \, dx. $$

As before, $L_2(\Omega)(\Omega)$ denotes the space of square summable functions with zero mean. Henceforth, we assume that

$$ f \in L_2(\Omega, \mathbb{R}^d), \quad u_0 \in W^1_2(\Omega, \mathbb{R}^d), $$

Mat-5.210 Special Course in Computational Mechanics, Autumn 2006, S. Repin
Generalized solution can be defined by the **integral identity**. It is a function \( u \in J^{1/2}_2(\Omega) + u_0 \) that meets the relation

\[
\int_{\Omega} \nu \nabla(u) : \nabla(v) \, dx = \int_{\Omega} f \cdot v \, dx \quad \forall v \in J^{1/2}_2(\Omega).
\] (245)

It is well known that \( u \) exists and unique and can be viewed as the minimizer of the functional

\[
I(v) = \int_{\Omega} \left( \frac{\nu}{2} |\nabla(v)|^2 - f \cdot v \right) \, dx
\]

on the set \( J^{1/2}_2(\Omega) + u_0 \). Thus, the problem

\[
\inf_{v \in J^{1/2}_2(\Omega) + u_0} I(v)
\]

presents a **variational formulation** of the Stokes problem.
Existence of a minimizer follows from known properties of convex lower semicontinuous functionals.
In addition, the Stokes problem can be presented in a minimax form.
Let \( L : (W_0 + u_0) \times L^2(\Omega) \rightarrow \mathbb{R} \) be defined as follows:

\[
L(v, q) = \int_{\Omega} \left( \frac{\nu}{2} |\nabla v|^2 - f \cdot v - q \text{div} v \right) \, dx.
\]

Now, \( u \) and \( p \) are defined as a saddle–point that satisfies the relations

\[
L(u, q) \leq L(u, p) \leq L(v, p) \quad \forall v \in W_0 + u_0, \ p \in L^2(\Omega).
\]
Extension of solenoidal fields and related results

First, we recall some basic results that has been established when the **solvability of the Stokes** problem was investigated. Works of O.A. Ladyzhenskaya have made a considerable and widely acknowledged contribution to the mathematical theory of viscous incompressible fluids.

**Lemma 1.**

For any vector-valued function $a \in W^{1/2}_2(\partial \Omega)$ satisfying the condition $\int_{\partial \Omega} a \cdot \nu \, dx = 0$ there exists a function $\bar{u} \in W_0$ such that $\text{div} \bar{u} = 0$ and

$$\| \nabla \bar{u} \| \leq \kappa_1(\Omega) \| a \|_{1/2, \partial \Omega},$$

(246)

where $\kappa_1(\Omega)$ is a positive constant that depends on $\Omega$. 
This lemma implies another proposition, which is of great importance for the analysis of problems defined on solenoidal fields.

**Lemma 2**

For any $f \in \mathcal{L}_2(\Omega)$ there exists a function $\bar{u} \in \mathcal{W}_0$ satisfying the relation $\text{div}\bar{u} = f$ and the condition

$$\|\nabla \bar{u}\| \leq \kappa_2(\Omega)\|f\|,$$

(247)

where $\kappa_2(\Omega)$ is a positive constant that depends on $\Omega$.

Lemma 2 implies several important corollaries that we discuss below.
Inf-Sup condition

Lemma 2 is related to the inequality known in the literature as the Inf-Sup—
or LBB (Ladyzhenskaya–Babuška–Brezzi)—condition that reads: there
eexists a positive constant $C$ such that

$$
\inf_{\phi \in L_2(\Omega), \phi \neq 0} \sup_{w \in W_0, w \neq 0} \frac{\int_{\Omega} \phi \text{div} w \, dx}{\|\phi\| \|\nabla w\|} \geq C. \quad (248)
$$
Lemma 2 implies LBB condition

By Lemma 2, any $\phi \in L_2(\Omega)$ has a counterpart function $v_\phi \in W_0$ that meets the conditions

$$\text{div} v_\phi = \phi, \quad \| \nabla v_\phi \| \leq \kappa_2(\Omega) \| \phi \|.$$ 

In this case,

$$\sup_{v \in W_0, v \neq 0} \frac{\int_{\Omega} \phi \text{div} v \, dx}{\| \nabla v \| \| \phi \|} \geq \frac{\int_{\Omega} \phi \text{div} v_\phi \, dx}{\| \nabla v_\phi \| \| \phi \|} = \frac{\| \phi \|}{\| \nabla v_\phi \|} \geq \frac{1}{\kappa_2(\Omega)}$$

and, consequently, Inf-Sup condition holds with

$$C = \frac{1}{\kappa_2(\Omega)}.$$
It is easy to observe that the Inf-Sup condition can be presented in the form
\[
\sup_{\substack{w \in W_0 \\ w \neq 0}} \left| \int_{\Omega} p \, \text{div} w \, dx \right| \geq C \| p \| \quad \text{for all } p \in L^2(\Omega).
\]

We may consider the expression in the left–hand side of the above inequality as the norm of $\nabla p$ in the space topologically dual to $W_0$, namely
\[
\left| \nabla p \right| := \sup_{w \in W_0} \frac{\langle \nabla p, w \rangle}{\| \nabla w \|}.
\]

Then, we arrive to the Nečas inequality.
Nečas inequality

\[ \| p \| \leq \kappa_2 \| \nabla p \| \quad \forall \ p \in \overset{\circ}{L}_2(\Omega), \]  

(249)

In the later paper, it is also shown that the well–known Korn’s inequality follows from Inf-Sup condition. Constants $C$ and $\kappa_2$ play an important role in the numerical analysis of the Stokes problem as well as in the theoretical one.
Existence of a saddle point

Existence of a saddle point of \( L(v, q) \) follows from Lemma 2 and known results of the minimax theory. In a simplified version these results reads:

Lagrangian \( L(v, q) \) possess a saddle point provided that
(a) it is convex and continuous with respect to the first variable and concave and continuous with respect to the second one;
(b) for a certain \( \bar{q} \) the functional \( v \mapsto L(v, \bar{q}) \) is coercive (or the set of admissible \( v \) is compact);
(c) or a certain \( \bar{v} \) the functional \( q \mapsto -L(\bar{v}, q) \) is coercive (or the set of admissible \( q \) is compact.)
Since

\[ J(v) = \sup_{q \in \Sigma} L(v, q) \geq L(\bar{q}, v), \]

we observe that (b) means that \( J(v) \) is coercive. Analogously, (c) means that the functional \(-I(q)\), where

\[ I(q) = \inf_{q \in V_0 + u_0} L(v, q) \leq L(q, \bar{v}), \]

is coercive.

In other words, for a continuous convex-concave Lagrangian existence of a saddle point mainly depends on the coercivity properties of the two dual functionals generated by it.
Let us apply these results to the Stokes problem. It is easy to see that for any \( q \in \dot{L}_2(\Omega) \) the mapping

\[
v \mapsto L(v, q) = \int_{\Omega} \left( \frac{\nu}{2} |\nabla v|^2 - f \cdot v - q \text{div} v \right) \, dx.
\]

is convex and continuous (in \( W \)) and there exists an element \( \bar{q} \in \dot{L}_2(\Omega) \) (e.g., \( \bar{q} = 0 \)) such that \( L(v, \bar{q}) \to +\infty \) if \( \|v\|_V \to +\infty \). The mapping \( q \mapsto L(v, q) \) is affine and continuous (in \( \dot{L}_2(\Omega) \)) for any \( v \in V \). Therefore, existence of a saddle point is guaranteed provided that the coercivity condition

\[
\lim_{\|q\| \to +\infty} \inf_{v \in W_0 + u_0} L(v, q) = -\infty \tag{250}
\]

is established. By Lemma 2 we can prove this fact.
Consider the functional

\[ I(q) := \inf_{v \in W_0 + u_0} L(v, q) \]

and the variational problem

\[ I(p) = \sup_{q \in \overset{\circ}{L}_2(\Omega)} I(q) \tag{251} \]

for the pressure function. Note that the functional \( I \) has no explicit integral-type form and is defined as a supremum–functional. The solvability of this problem follows from the coercivity condition (250). To prove (250) we apply Lemma 2.
Coercivity of the variational problem for the pressure function

Indeed, by Lemma 2 for any \( q \in L_2(\Omega) \) we find \( v_q \in W_0 \) such that

\[
\text{div} v_q = q \quad \text{and} \quad \|\nabla v_q\| \leq \kappa_2 \|q\|.
\]

Take \( v = \mu v_q + u_0 \) and recall that \( \text{div} u_0 = 0 \). Then,

\[
\inf_{v \in W_0 + u_0} L(v, q) \leq \int_{\Omega} \left( \frac{\nu}{2} |\nabla (\mu v_q + u_0)|^2 - f \cdot (\mu v_q + u_0) - q \text{div} (\mu v_q + u_0) \right) dx \leq \\
\leq \int_{\Omega} \left( \frac{\nu}{2} |\nabla u_0|^2 - f \cdot u_0 \right) dx + \mu (\nu \|\nabla u_0\| + C_\Omega \|f\|) \|\nabla v_q\| + \\
+ \frac{\nu \mu^2}{2} \|\nabla v_q\|^2 - \mu \|q\|^2 \leq \int_{\Omega} \left( \frac{\nu}{2} |\nabla u_0|^2 - f \cdot u_0 \right) dx + \\
+ \mu (\nu \|\nabla u_0\| + C_\Omega \|f\|) \kappa_2 \|q\| + \mu \left( \frac{\nu \mu \kappa_2^2}{2} - 1 \right) \|q\|^2,
\]

where \( C_\Omega \) is a constant in the Friederichs inequality.
We see that
\[ I(q) \leq c_1(u_0, f, \nu) + \mu(\nu \| \nabla u_0 \| + C_\Omega \| f \|) \kappa_2 \| q \| + \mu \left( \frac{\nu \mu \kappa_2^2}{2} - 1 \right) \| q \|^2. \]

Set here \( \mu = \frac{1}{\nu \kappa_2^2} \). Then
\[ \inf_{v \in W_0 + u_0} L(v, q) \leq c_1 + c_2 \| q \| - \frac{1}{2 \nu \kappa_2^2} \| q \|^2 \rightarrow -\infty \text{ as } \| q \| \rightarrow +\infty. \]

Thus, we observe that the constant \( \kappa_2 \) arises in the quadratic term that provides the required coercivity property of the pressure functional.
Estimates of the distance to the set of solenoidal fields

Now we are concerned with the estimates of the distance between a function \( \mathbf{v} \in H^1 \) and the space of solenoidal functions. **Estimates in L2-norm.** An estimate of the distance between \( \mathbf{v} \) and the space

\[
J_2^1(\Omega) := \left\{ \mathbf{v} \in W_2^1(\Omega) \mid \text{div}
\mathbf{v} = 0 \right\}
\]

in L2–norm follow from the solvability of the Dirichlet problem for the Laplace operator. It is as follows:

\[
\inf_{\mathbf{v}_0 \in J_2^1} \| \mathbf{v} - \mathbf{v}_0 \| \leq C_F \| \text{div}
\mathbf{v} \|
\]

where \( C_F \) is the constant in the Friederichs inequality.
\textbf{Proof.} Indeed, since the problem

$$\Delta \phi = f,$$

has a solution $\phi \in \hat{W}^1_2(\Omega)$ for any $f \in L_2(\Omega)$, we conclude that for any $f$ there exists $v_f = \nabla \phi$ such that

$$\text{div} v_f = f \quad \text{and} \quad \|v_f\| \leq C_F \|f\|.$$  

Set $f = \text{div} \hat{\nabla}$. Then,

$$\text{div}(v_f - \hat{\nabla}) = 0,$$

so that $v_0 = v_f - \hat{\nabla}$ belongs to $J^1_2$ and we observe that

$$\|\hat{\nabla} - v_0\| \leq C_F \|\text{div} \hat{\nabla}\|.$$
Estimate in $H^1$-norm. Let now $\widehat{v} \in H^1$. Set $f = \text{div}\widehat{v}$. Since

$$\int_{\Omega} \text{div}\widehat{v} \, dx = \int_{\partial\Omega} v \cdot \nu \, ds = 0,$$

we see that $f \in \dot{L}_2(\Omega)$. Then, by Lemma 2, one can find $u_f \in W_0$ such that

$$\text{div}u_f = \text{div}\widehat{v}, \quad \text{and} \quad \|\nabla u_f\| \leq \kappa_2(\Omega)\|\text{div}\widehat{v}\|.$$

In other words, there exists a solenoidal field $w_0 = (\widehat{v} - u_f) \in W_0$ such that

$$\|\nabla(\widehat{v} - w_0)\| = \|\nabla u_f\| \leq \kappa_2(\Omega)\|\text{div}\widehat{v}\|.$$
This fact can be presented in another form

\[ \inf_{\nabla \hat{\mathbf{v}} \in \mathcal{J}^1_2(\Omega)} \| \nabla (\hat{\mathbf{v}} - \mathbf{v}) \| \leq \kappa_2(\Omega) \| \text{div} \mathbf{v} \|. \]  

(252)

Thus, for the functions with zero traces the distance to \( \mathcal{J}^1_2(\Omega) \) in a strong norm is also measured via \( \| \text{div} \mathbf{v} \| \), but with a different factor: \( \kappa_2(\Omega) \).
Comments on the value of $C$

Note that $C$ can be estimated throughout the constant $C_f$ and the constant $C_p$ in the Poincare inequality. Indeed,

$$C = \inf_{q \in L^2(\Omega), q \neq 0} E(q),$$

$$E(q) = \sup_{w \in W_0, w \neq 0} \frac{\int_{\Omega} q \text{div} w \, dx}{\|q\| \|\nabla w\|}.$$

For $q \in \tilde{W}(\Omega) := L^2(\Omega) \cap W^{1,2}_0(\Omega)$ we have

$$E(q) = \sup_{w \in W_0, w \neq 0} \frac{\int_{\Omega} \nabla q \cdot w \, dx}{\|q\| \|\nabla w\|} \leq \frac{\|\nabla q\|}{\|q\|} \sup_{w \in W_0, w \neq 0} \frac{\|w\|}{\|\nabla w\|} \leq C_f \frac{\|\nabla q\|}{\|q\|}.$$
Let $C_P$ be the smallest constant in the inequality

$$\|q\| \leq C_P \|\nabla q\|, \quad q \in \tilde{W}(\Omega),$$

i.e.,

$$\inf_{q \in \tilde{W}(\Omega), \, q \neq 0} \frac{\|\nabla q\|}{\|q\|} = \frac{1}{C_P}.$$

Then

$$C = \inf_{q \in L^2(\Omega), \, q \neq 0} \mathcal{E}(q) \leq \inf_{q \in \tilde{W}(\Omega), \, q \neq 0} \mathcal{E}(q) \leq \frac{C_F}{C_P}.$$
LBB-condition can be written in the form

\[ \|p\| \leq C^{-1} |\nabla p| \quad \forall \ p \in \overset{.}{L}_2(\Omega), \]

what amounts

\[ C \leq \frac{|\nabla p|}{\|p\|} \]

we see the meaning of this constant: \( C \) is the infimum of \( H^{-1} \) norms of functions such that \( \|p\| = 1 \) and \( \int_{\Omega} p \, dx = 0 \).

**Proposition 1**

If \( \Omega \in \mathbb{R}^n \) then

\[ \frac{\|\nabla p\|_{(-1)}}{\|p\|} \leq n \quad \forall p \in L_2(\Omega). \]
Proof.

\[
\sup_{\Omega} \frac{\int p \text{div} w \, dx}{\| \nabla w \|} = \sup_{\Omega} \frac{\sum_{t=1}^{n} \int p w_{t,t} \, dx}{\| \nabla w \|} \leq \sum_{t=1}^{n} \sup_{\Omega} \frac{\int p w_{t,t} \, dx}{\| \nabla w \|}.
\]
Since

\[ \| \nabla w \|^2 = \int_{\Omega} \left( \sum_{t,s=1}^{n} w_{t,s}^2 \right) \, dx \geq \int_{\Omega} w_{t,t}^2 \, dx \quad \forall t = 1, 2, \ldots, n \]

we have

\[
\sup_{w \in W_0 \atop w \neq 0} \frac{\int \nabla \cdot p \, w \, dx}{\| \nabla w \|} \leq \sum_{t=1}^{n} \sup_{w_t \in H^1 \atop w_t \neq 0} \frac{\int p \, w_t \, dx}{\| w_t \|} \leq \sum_{t=1}^{n} \frac{\int p \eta \, dx}{\| \eta \|} = \sum_{t=1}^{n} \| p \| = n \| p \| .
\]
Proposition 2

If \( n = 1 \) then \( C = 1 \).

Let \( \Omega = (a, b) \). Due to Proposition 1 we see that \( C \leq 1 \). Let \( p \) be an arbitrary function from the set \( L_2(\Omega) \). Then, the function

\[
w^{(p)} = \int_a^x p \, dx \in W_0.
\]

Really, \( w^{(p)}(a) = 0 \), \( w^{(p)}(b) = \int_a^b p \, dx = 0 \) and \( w^{(p)'} = p \in L_2(a, b) \). Thus,

\[
\sup_{\substack{w \in W_0 \\ w \neq 0}} \frac{\int_\Omega p \, w' \, dx}{\|w'\|} \geq \frac{\int_\Omega p \, w^{(p)'} \, dx}{\|w^{(p)'}\|} = \frac{\int_\Omega p^2 \, dx}{\|p\|} = \|p\|
\]

Thus, \( C \geq 1 \) and we arrive at the required result.
These estimates give a certain presentation on the value of $C$. However, we are mainly interested in the estimate from below, what imposes a task more complicated than the finding the constant in the Friederichs inequality. In principle, one could determine $C$ by the following arguments. Let $w_p \in W_0$ be a function such that

$$\Delta w_p = \nabla p, \quad w_p = 0 \text{ on } \partial \Omega.$$  

Then,

$$- \int_{\Omega} \nabla w_p : \nabla v \, dx = \int_{\Omega} \nabla p \cdot v \, dx \quad \forall v \in W_0$$

and, thus, we have

$$\int_{\Omega} |\nabla w_p|^2 \, dx = \int_{\Omega} p \text{ div} w_p \, dx \quad \forall v \in W_0.$$
Therefore,

\[
C := \inf_{\substack{p \in \mathcal{L}_2(\Omega) \setminus \{0\}}} \sup_{w \in W_0 \setminus \{0\}} \frac{\int_{\Omega} p \text{div} w \, dx}{\|p\| \|\nabla w\|} \geq \inf_{\substack{p \in \mathcal{L}_2(\Omega) \setminus \{0\}}} \frac{\int_{\Omega} p \text{div} w_p \, dx}{\|p\| \|\nabla w_p\|} = \inf_{\substack{p \in \mathcal{L}_2(\Omega) \setminus \{0\}}} \frac{\|\nabla w_p\|}{\|p\|}.
\]

Thus, finding \(C\) requires the minimization of this quotient with respect to all \(p \in \mathcal{L}_2(\Omega)\), where \(w_p\) is taken as the solution of the above defined linear problem. Certainly, such a task (for some \(\Omega\)) might be solved by only analytical methods.
We will use the above relation to minimize the quotient on a subspace of $\mathcal{L}_2(\Omega)$ what may give a presentation on the value of $C$.

Let

$$\Omega = \mathcal{Q} := \{ x \in \mathbb{R}^n \mid x_i \in (-\pi, \pi), \ i = 1, 2, \ldots n \} .$$

We are interested in the value of the quotient

$$\inf_{p \in \mathcal{L}_2(\Omega)} \frac{||\nabla p||}{||p||_Q} .$$

Represent $p$ as a series with respect to the trial functions

$$p^{(1)}_{ij} = \sin ix \sin jy, \quad p^{(2)}_{ij} = \sin ix \cos jy,$$

$$p^{(3)}_{ij} = \cos ix \sin jy, \quad p^{(4)}_{ij} = \cos ix \cos jy ,$$

where $i, j = 0, 1, 2, \ldots$
Then

\[ p(x, y) = \sum_{i,j=0}^{\infty} \sum_{s=1}^{4} a_{ij}^{(s)} p_{ij}^{(s)}. \]

Here, the first nonzero coefficients are

\[ a_{00}^{(4)} = \frac{1}{4\pi^2} \int_{\Omega} p \, dx \, dy, \quad a_{i0}^{(2)} = \frac{1}{2\pi^2} \int_{\Omega} p \sin ix \, dx \, dy, \]
\[ a_{0j}^{(3)} = \frac{1}{2\pi^2} \int_{\Omega} p \sin jy \, dx \, dy, \]
\[ a_{i0}^{(4)} = \frac{1}{2\pi^2} \int_{\Omega} p \cos ix \, dx \, dy, \]
\[ a_{0j}^{(2)} = \frac{1}{2\pi^2} \int_{\Omega} p \cos jy \, dx \, dy, \]
Other coefficients are as follows:

\[ a_{ij}^{(1)} = \frac{1}{\pi^2} \int_{\Omega} p \sin ix \sin jy \, dx \, dy , \]

\[ a_{ij}^{(2)} = \frac{1}{\pi^2} \int_{\Omega} p \sin ix \cos jy \, dx \, dy , \]

\[ a_{ij}^{(3)} = \frac{1}{\pi^2} \int_{\Omega} p \cos ix \sin jy \, dx \, dy , \]

\[ a_{ij}^{(4)} = \frac{1}{\pi^2} \int_{\Omega} p \cos ix \cos jy \, dx \, dy . \]

We have

\[ \| p \|_Q^2 = \pi^2 \sum_{i,j=0}^{\infty} \lambda_{ij} \left[ (a_{ij}^{(1)})^2 + (a_{ij}^{(2)})^2 + (a_{ij}^{(3)})^2 + (a_{ij}^{(4)})^2 \right] , \]

where \( \lambda_{00} = 0, \lambda_{01} = 2, \lambda_{10} = 2 \) and \( \lambda_{ij} = 1 \) for all \( i, j \geq 1 \).
Let us take a finite number of elements in the Fourier series for $\mathbf{p}$:

$$\mathbf{p} = \sum_{i,j=0}^{N} \sum_{s=1}^{4} a_{ij}^{(s)} \mathbf{p}_{ij}^{(s)},$$

where $a_{ij}^{(s)}$ are the above defined coefficients. Since

$$|\nabla \mathbf{p}| = \sup_{\mathbf{v} \in \mathcal{W}_0} \frac{\int \mathbf{p} \text{div} \mathbf{v} \, dx}{\|\nabla \mathbf{v}\|_Q}$$

we need to introduce the system of trial functions in $\mathcal{W}_0(Q)$. It is given by the system of eigenfunctions for the problem

$$\Delta \mathbf{w} = \mu \mathbf{w} \quad \mathbf{w}|_{\partial Q} = 0.$$
This system is

\[ \phi_{\alpha\beta} = \sin \frac{\alpha}{2} (x + \pi) \sin \frac{\beta}{2} (y + \pi). \]

In this case,

\[ \phi_{\alpha\beta,1} = \frac{\alpha}{2} \cos \frac{\alpha}{2} (x + \pi) \sin \frac{\beta}{2} (y + \pi), \]
\[ \phi_{\alpha\beta,2} = \frac{\beta}{2} \sin \frac{\beta}{2} (x + \pi) \cos \frac{\beta}{2} (y + \pi). \]

Take a finite number \( M \) of basic functions in the representation of \( \mathbf{v} \), namely we set

\[ \mathbf{v} = \mathbf{v}^M = (\mathbf{v}^M_1, \mathbf{v}^M_2), \quad \mathbf{v}_1^M = \sum_{\alpha, \beta = 1}^{M} \mathbf{b}_{\alpha\beta} \phi_{\alpha\beta}, \quad \mathbf{v}_2^M = \sum_{\alpha, \beta = 1}^{M} \mathbf{c}_{\alpha\beta} \phi_{\alpha\beta}. \]

The set of all such functions we denote \( \mathcal{W}_0^M \). In this case, we can obtain a lower bound for the required norm. Really, we have
\[
\| \nabla p \|^{(M)} := \sup_{v^M \in W_0^M} \frac{\int \Omega p \, \text{div} v^M \, dx}{\|\nabla v^M\|_Q} \leq \| \nabla p \| = \sup_{v \in W_0} \frac{\int \Omega p \, \text{div} v \, dx}{\|\nabla v\|_Q}.
\]

Thus, we may hope to estimate the value of the quotient

\[
\inf_{p \in L_2(\Omega)} \frac{\| \nabla p \|}{\| p \|_Q}.
\]

by taking \( N, M \rightarrow +\infty \), \( M = \kappa N \) \( \kappa \) is essentially larger than 1 (typically 8-20). Numerical results for different \( N \) are exposed below.
Minimizer $p_n$ for $n = 8, 36$ and $120$. 

Mat-5.210 Special Course in Computational Mechanics, Autumn 2006, S. Repin
Deviation estimates for the Stokes problem

In order to clarify the main ideas of our approach we rewrite the classical Stokes system in a somewhat different form:

\[ \text{div} \sigma = \nabla p - f \quad \text{in} \; \Omega, \quad (253) \]
\[ \text{div} u = 0 \quad \text{in} \; \Omega, \quad (254) \]
\[ \sigma = \nu \nabla u \quad \text{in} \; \Omega, \quad (255) \]
\[ u = 0 \quad \text{on} \; \partial \Omega. \quad (256) \]

This system involves one additional variable \( \sigma \) that corresponds to the field of stresses. Now we may regard the Stokes problem as the problem of finding a triplet of functions \((u, \sigma, p)\).
Primal and Dual Problems

Functional formulations of the above problem are given in natural "energy" set for this velocity–stress-pressure setting, which is

\[ \mathcal{E} := \mathcal{J}^1_2(\Omega) \times \boldsymbol{\Sigma} \times \mathcal{L}^2(\Omega). \]

**Problem** $\mathcal{P}$. Find $u \in \mathcal{J}^1_2(\Omega)$ such that

\[ \mathcal{J}(u) \leq \mathcal{J}(v) \quad \text{for all} \quad v \in \mathcal{J}^1_2(\Omega), \]

where

\[ \mathcal{J}(v) = \int_{\Omega} \left( \frac{\nu}{2} |\nabla v|^2 - f \cdot v \right) \, dx. \]

We denote the exact lower bound of this problem by $\inf \mathcal{P}$. 
Introduce the Lagrangian $L : J^{{\Delta \frac{1}{2}}}(\Omega) \times \Sigma(\Omega) \rightarrow \mathbb{R}$:

$$
L(v, \tau) = \int_{\Omega} \left( \tau : \nabla v - \frac{1}{2\nu} |\tau|^2 \right) \, dx - \int_{\Omega} fv \, dx
$$

that together with Problem $P$ generates the dual problem

$$
\sup_{\tau \in \Sigma} \inf_{v \in J^{{\Delta \frac{1}{2}}}(\Omega)} L(v, \tau)
$$

which is **Problem $P^*$**: find $\sigma \in \Sigma_f$ such that

$$
I^*(\sigma) = \sup_{\tau \in \Sigma_f} I^*(\tau), \quad I^*(\tau) = -\frac{1}{2\nu} \int_{\Omega} |\tau|^2 \, dx
$$

where

$$
\Sigma_f := \left\{ \tau \in \Sigma(\Omega) \mid \int_{\Omega} \tau : \nabla w \, dx = \int_{\Omega} fw \, dx \text{ for all } w \in J^{{\Delta \frac{1}{2}}}(\Omega) \right\}.
$$
From the general theorems of convex analysis it follows

**Theorem (1)**

There exists a unique minimizer $u$ of problem $\mathcal{P}$ and unique maximizer $\sigma$ of problem $\mathcal{P}^*$. These two functions meet the equalities

$$I^*(\sigma) = \sup \mathcal{P}^* = \inf \mathcal{P} = l(u),$$

$$\sigma = \nu \nabla u.$$
The basic error relation for the Stokes problem is given by the following theorem (S. Repin, 2002).

**Theorem (2)**

For any \( \mathbf{v} \in \mathbf{J}_{1/2}(\Omega) \) and any \( \mathbf{\tau}_f \in \Sigma_f \), we have

\[
\nu \| \nabla (\mathbf{v} - \mathbf{u}) \|^2 + \frac{1}{\nu} \| \mathbf{\tau}_f - \mathbf{\sigma} \|^2 = 2 \left( J(\mathbf{v}) - I^*(\mathbf{\tau}_f) \right). \tag{259}
\]
Proof of Theorem 2

Since $u$ is the solution of problem $\mathcal{P}$, we obtain

$$J(v) - J(u) = \int_{\Omega} \left( \frac{\nu}{2} |\nabla v|^2 - \frac{\nu}{2} |\nabla u|^2 - f \cdot (v - u) \right) \, dx =$$

$$= \int_{\Omega} \left( \frac{\nu}{2} |\nabla (v - u)|^2 + \nu \nabla u : \nabla (v - u) - f \cdot (v - u) \right) \, dx =$$

$$= \frac{\nu}{2} \int_{\Omega} |\nabla (v - u)|^2 \, dx \quad \text{for all } v \in \mathcal{H}^1_0(\Omega).$$

Since $J(u) = \inf \mathcal{P}$, we conclude that

$$\frac{\nu}{2} \|\nabla (v - u)\|^2 = J(v) - \inf \mathcal{P} \quad \text{for all } v \in \mathcal{H}^1_0(\Omega).$$
The next step is to derive a similar relation for the dual problem. For this purpose, we note that the maximizer $\sigma$ of problem $\mathcal{P}^*$ satisfies the relation

$$\int_{\Omega} \sigma : (\tau_f - \sigma) \, dx = 0 \quad \text{for all } \tau_f \in \Sigma_f.$$ 

By virtue of this relation, we find that

$$\sup_{\mathcal{P}} \mathcal{P}^* - l^*(\tau_f) = l^*(\sigma) - l^*(\tau_f) = \frac{1}{2\nu} \|\tau_f - \sigma_f\|^2 \quad \tau_f \in \Sigma_f.$$ 

Since $\inf \mathcal{P} = \sup \mathcal{P}^*$ we sum the two equalities and obtain

$$\nu \|\nabla (v - u)\|^2 + \frac{1}{\nu} \|\tau_f - \sigma\|^2 = 2 (J(v) - l^*(\tau_f)).$$
Stokes problem is a particular case of the abstract problem we investigated in Lecture 5:

Find \( u \in V_0 + u_0 \) such that

\[
(\mathcal{A}\Lambda u, \Lambda w) + \langle \ell, w \rangle = 0 \quad \forall w \in V_0.
\]

In this case \( V_0 = \mathcal{J}_2^1(\Omega) \), \( V \) is a subspace of \( H^1 \) containing solenoidal fields, \( \Lambda = \nabla \) (tensor-gradient), \( U = \Sigma \), \( \mathcal{A}y = \nu y \), and

\[
\langle \ell, w \rangle = - \int_{\Omega} fw \, dx
\]
Thus, we can apply the estimate

$$\frac{1}{2} \| \Lambda (v - u) \|^2 \leq (1 + \beta) D(\Lambda v, y) + \frac{1 + \beta}{2\beta} \| \ell + \Lambda^* y \|^2,$$

(260)

where $\| y \|^2 = \int_{\Omega} \nu |y|^2 dx$ and

$$\| \ell + \Lambda^* y \| = \sup_{w \in V_0} \frac{\langle \ell + \Lambda^* y, w \rangle}{\| \Lambda w \|} = \sup_{\omega \in L^2(\Omega)} \frac{\int_\Omega (\nabla w : y - f w) dx}{\| \nabla w \|}$$

$$\leq \sup_{w \in H^1(\Omega)} \frac{\int_\Omega (\nabla w : y - f w - q \text{div} w) dx}{\| \nabla w \|} \quad \forall q \in L^2(\Omega).$$
If

\[ y \in \Sigma_{\text{div}}(\Omega) := \{ y \in \Sigma \mid \text{div} y \in L^2(\Omega, \mathbb{R}^n) \} \]

and \( q \in H^1 \), we have

\[
\int_{\Omega} (\nabla w : y - fw - q\text{div}w) \, dx = \int_{\Omega} (f - \nabla q + \text{div}y) \cdot w \, dx
\]

Since

\[
\|w\| \leq C_\Omega \|\nabla w\| = C_\Omega \nu^{-1/2} \|\nabla w\|,
\]

we obtain

\[
\|\mathcal{L} + \Lambda^* y\| \leq C_\Omega \nu^{-1/2} \|f - \nabla q + \text{div}y\|
\]
Further,

\[
D(\nabla v, y) = \int_\Omega \left( \frac{1}{2} \nu \nabla v : \nabla v + \frac{1}{2} \nu^{-1} y : y - \nabla v : y \right) \, dx =
\]

\[
= \frac{1}{2\nu} \|y - \nu \nabla v\|^2.
\]

Now, from (260) we obtain

\[
\frac{\nu}{2} \|\nabla (u - v)\|^2 \leq (1 + \beta) \frac{1}{2\nu} \|y - \nu \nabla v\|^2 + \frac{1 + \beta}{2\beta \nu} C_\Omega^2 \|f - \nabla q + \text{div} y\|^2,
\]

or

\[
\nu^2 \|\nabla (u - v)\|^2 \leq (1 + \beta) \|y - \nu \nabla v\|^2 + \frac{1 + \beta}{\beta} C_\Omega^2 \|f - \nabla q + \text{div} y\|^2.
\]
Deviation estimate for solenoidal approximations

By the minimization with respect to $\beta$ we derive the first basic estimate for the Stokes problem:

$$\nu \| \nabla (u - v) \| \leq \| y - \nu \nabla v \| + C_\Omega \| f - \nabla q + \text{div} y \|.$$  \hfill (261)

Here $v$ is any conforming approximation of $u$ and $y$ is any tensor–function in $\Sigma_{\text{div}}(\Omega)$ and $q \in H^1$ is an ”image” of the pressure function. This and the next estimate for non-solenoidal approximations has been derived in ’99, English translation is presented in S. Repin. A posteriori estimates for the Stokes problem, \textit{J. Math. Sci. (New York)}, \textbf{109} (2002).
If the function $\hat{v} \in V_0 + u_0$ does not satisfy the incompressibility condition, then the estimate of its deviation from $u$ can be obtained as follows. By Lemma 2 for the function $\hat{v}_0 := \hat{v} - u_0$ one can find a function $w_0 \in J_2^1(\Omega)$ such that

$$\|\nabla(\hat{v}_0 - \hat{w}_0)\| \leq \kappa_2(\Omega)\|\text{div}\hat{v}_0\|.$$

Then,

$$\nu\|\nabla(u - \hat{v})\| = \nu\|\nabla(u - \hat{v}_0 - u_0)\| \leq \nu\|\nabla(u - (\hat{w}_0 + u_0))\| + \nu\|\nabla(\hat{v}_0 - \hat{w}_0)\|.$$

Use (261) to estimate the first norm in the right-hand side of this inequality.
We obtain

\[ \nu \| \nabla (u - \hat{v}) \| \leq \| \nu \nabla (\hat{w}_0 + u_0) - y \| + C_\Omega \| \text{div} y + f - \nabla q \| + \]
\[ + \nu \| \nabla (\hat{v}_0 - \hat{w}_0) \| \leq \| \nu \nabla \hat{v} - y \| + \]
\[ + C_\Omega \| \text{div} y + f - \nabla q \| + 2\nu \| \nabla (\hat{v}_0 - \hat{w}_0) \|. \]

Hence, we arrive at the estimate

\[ \nu \| \nabla (u - \hat{v}) \| \leq \| \nu \nabla (\hat{v}) - y \| + C_\Omega \| \text{div} y + f - \nabla q \| + \frac{2\nu}{C} \| \text{div} \hat{v} \|. \] (262)

Three terms in the right-hand side of the estimate present three natural parts of the error, namely \textit{errors in the constitutive law, differential equation and incompressibility condition}. 

Mat-5.210 Special Course in Computational Mechanics, Autumn 2006, S. Repin

Helsinki University of Technology

A POSTERIORI ANALYSIS FOR PDE's.
Another form of the Majorant

Set $\mathbf{y} = \eta + qI$, where $I$ is the unit tensor and $\eta \in \Sigma_{\text{div}}(\Omega)(\Omega)$. Then the Majorant comes in the form

$$\nu \| \nabla (\mathbf{u} - \widehat{\mathbf{v}}) \| \leq \| \nu \nabla (\widehat{\mathbf{v}}) - \eta - qI \| + C_{\Omega} \| \text{div} \eta + f \| + \frac{2\nu}{C} \| \text{div} \widehat{\mathbf{v}} \|. \quad (263)$$

Thus, if the constants $c_{\Omega}$ and $C$ are known (or we know suitable upper bounds for them), then (262) and (263) provides a way of practical estimation the deviation of $\widehat{\mathbf{v}}$ from $\mathbf{u}$. 
Practical implementation

To use the above estimates in practice we should select certain finite dimensional subspaces

$$\Sigma_k$$ and $$Q_k$$

for the functions $$y$$ (or $$\eta$$ ) and $$q$$, respectively.
Minimization of the right–hand side of the estimates with respect to $$y$$ and $$q$$ gives an estimate of the deviation, which will be the sharper the greater is the dimensionality of the subspaces used.
Estimates for the pressure field

Let \( q \in L_2(\Omega) \) be an approximation of the pressure field \( p \). Then \( (p - q) \in L_2(\Omega) \) and the Inf-Sup condition implies the relation

\[
\sup_{w \in V_0, w \neq 0} \frac{\int_\Omega (p - q) \text{div} w \, dx}{\|p - q\| \|\nabla w\|} \geq C.
\]

Thus, for any small positive \( \epsilon \) there exists a nonzero function \( w_{pq}^\epsilon \in V_0 \) such that

\[
\int_\Omega (p - q) \text{div} w_{pq}^\epsilon \, dx \geq (C - \epsilon) \|p - q\| \|\nabla w_{pq}^\epsilon\|.
\]
Since
\[
\int_{\Omega} \nu \varepsilon(u) : \varepsilon(w_{pq}) \, dx = \int_{\Omega} \left( f \cdot w_{pq} + p \text{div} w_{pq} \right) \, dx,
\]
we have
\[
\int_{\Omega} (p - q) \text{div} w_{pq} \, dx = \int_{\Omega} \left\{ \nu \varepsilon((u - \hat{v}) : \varepsilon(w_{pq}) + \left( \nu \varepsilon(\hat{v}) : \varepsilon(w_{pq}) + \nabla q \cdot w_{pq} - f \cdot w_{pq} \right) \right\} \, dx
\]
\[
= \int_{\Omega} \nu \varepsilon((u - \hat{v}) : \varepsilon(w_{pq}) \, dx + \int_{\Omega} (\nu \varepsilon(\hat{v} - y) : \varepsilon(w_{pq}) \, dx
\]
\[
+ \int_{\Omega} (y : \varepsilon(w_{pq}) + \nabla q \cdot w_{pq} - f \cdot w_{pq}) \, dx,
\]
where \( \hat{v} \) is an arbitrary function in \( W_0 + u_0 \) and \( y \) as an arbitrary tensor-valued function in \( \Sigma \).
Above relations lead to the estimates

\[ \|p - q\| \leq \frac{1}{(C - \epsilon)\|\nabla w_{pq}\|} \]

\[ \times \left[ \int_{\Omega} (\nu \epsilon(u - \hat{v}) : \epsilon(w_{pq}^\epsilon) + (\nu \epsilon(\hat{v}) - y) : \epsilon(w_{pq}^\epsilon)) \, dx \right. \]

\[ + \int_{\Omega} (-w_{pq}^\epsilon \cdot \text{div}y + \nabla q \cdot w_{pq}^\epsilon - f \cdot w_{pq}^\epsilon) \, dx \right] \]

\[ \leq \frac{1}{(C - \epsilon)} \left[ \nu \|\epsilon(u - \hat{v})\| + \|\nu \epsilon(\hat{v}) - y\| + C_\Omega \|\text{div}y + f - \nabla q\| \right]. \]

The first term in the right-hand side of this inequality is estimated by (262).
Deviation estimate for the pressure function

Since $\epsilon$ may be taken arbitrarily small, we obtain the following estimate for the deviation from the exact pressure field:

$$
\frac{1}{2} \| p - q \| \leq \frac{\nu}{C^2} \| \text{div} \hat{v} \| + \\
+ \frac{1}{C} \| \mu \epsilon(\hat{v}) - y \| + \frac{C_\Omega}{C} \| \text{div} y + \mathbf{f} - \nabla q \|.
$$

(264)

It is easy to see that the right–hand side of (264) consists of the same terms as the right–hand side of (262) and vanishes if and only if, $\hat{v} = \mathbf{u}$, $y = \sigma$ and $p = q$. However, in this case, the dependence of the penalty multipliers from the constant $C$ is stronger.
Problems with condition $\text{div} u = \phi$.

In many cases, divergence–free condition is replaced by

$$\text{div} u = \phi \quad \text{in } \Omega,$$

where $\phi$ is a given function in $L_2(\Omega)$. For such functions, we have the problem: find $u$ that is equal to $u_0$ on $\partial \Omega$ and

$$-\text{div} \sigma + \nabla p = f \quad \text{in } \Omega,$$
$$\sigma = \nu \varepsilon(u) \quad \text{in } \Omega,$$

Let $u_\phi \in W_0$, $\text{div} u_\phi = \phi$. By setting $u = \bar{u} + u_\phi$ and $\bar{u}_0 = u_0 - u_\phi$, we present the boundary–value problem as follows: find $\bar{u} \in J^{1}_{2}(\Omega) + \bar{u}_0$ such that

$$-\text{div} \bar{\sigma} + \nabla p = \bar{f} \quad \text{in } \Omega,$$
$$\bar{\sigma} = \nu \varepsilon(\bar{u}) \quad \text{in } \Omega.$$
Assume that \( u \) is approximated by a certain \( v \in V_0 + u_0 \). Let \( v \) be presented in the form \( v = \tilde{v} + u_\phi \). Now, we apply (262) to a ”shifted” system and obtain

\[
\| \varepsilon (u - v) \| = \| \varepsilon (\tilde{u} - \tilde{v}) \| \leq \leq \| \nu \varepsilon (\tilde{v}) - y \| + [ \text{div} y + \bar{f} - \nabla q ] + \frac{2\nu}{C_{\text{LBB}}} \| \text{div} \tilde{v} \|.
\]

Set here \( y = -\nu \nabla (u_\phi) + \eta \), where \( \eta \) is a function in \( \Sigma_{\text{div}} \). Then

\[
\text{div} y + \bar{f} = -\nu \text{div} \varepsilon (u_\phi) + \text{div} \eta + \bar{f} = \text{div} \eta + f
\]

and \( \nu \varepsilon (\tilde{v}) - y = \nu \varepsilon (v - u_\phi) - y = \nu \varepsilon (v) - \eta \). Therefore,

\[
\| \varepsilon (u - v) \| \leq \leq \| \nu \varepsilon (v) - \eta \| + [ \text{div} \eta + f - \nabla q ] + \frac{2\nu}{C_{\text{LBB}}} \| \text{div} v - \phi \|.
\]
Problems for almost incompressible fluids

Models of almost incompressible fluids are often used for constructing sequences of functions converging to a solution of the Stokes problem. In this case, the incompressibility condition is replaced by a penalty term: find \( u_\delta \in V \) satisfying the integral identity

\[
\int_{\Omega} \left( \nu \nabla u_\delta : \nabla w + \frac{1}{\delta} \text{div} u_\delta \text{div} w \right) \, dx = \int_{\Omega} f \cdot w \, dx, \quad w \in W_0,
\]

and the boundary condition \( u_\delta = u_0 \) on \( \partial \Omega \).

It is not difficult to show (see, e.g., R. Temam. NS Equations), that \( u_\delta \) tends to \( u \) (solution of the Stokes problem) in \( H^1 \) norm and

\[
p_\delta = -\frac{1}{\delta} \text{div} u_\delta \in L^2(\Omega)
\]

converges to the respective pressure function \( p \) in \( L^2 \) as \( \delta \to 0 \).
By (262) we can easily obtain an estimate of the difference between $u$ and $u_\delta$. Let us set in (262) $y = \tau_\delta := \nu \nabla u_\delta$ and $q = p_\delta = -\frac{1}{\delta} \text{div} u_\delta$. In this case, $\| \nu \nabla u_\delta - \tau_\delta \| = 0$ and

$$\left| \text{div} \tau_\delta + f - \nabla p_\delta \right| =$$

$$= \sup_{w \in \mathcal{V}_0} \frac{\int_\Omega (-\nu \nabla u_\delta : \nabla w + f \cdot w + p_\delta \text{div} w) \, dx}{\|\nabla w\|} = 0.$$

Thus, we conclude that

$$\frac{1}{2} \|\nabla (u - u_\delta)\| \leq \frac{1}{C_{\text{LBB}}} \| \text{div} u_\delta \|,$$

We observe that the deviation from the exact solution of the Stokes problem is controlled by the norm of the divergence of the regularized problem. Similar estimate can be obtained for the approximations constructed by means of the Uzawa algorithm.
Functional a posteriori estimates for the Stokes and some other problems were also derived by nonvariational techniques (see S. Repin. *St.-Petersburg Math. J.*, (2004)). In particular, such estimates were derived for the Oseen problem

\[-\nu \Delta u + \text{div}(a \otimes u) = f - \nabla p \quad \text{in } \Omega,\]

\[\text{div} u = 0 \quad \text{in } \Omega,\]

\[u = 0 \quad \text{on } \partial \Omega.\]
A posteriori estimates of the above discussed type can be derived in the abstract form for the whole class of problems where a solution is seeking in a subspace. Typically, we have the following diagram:

\[
\begin{array}{cccccc}
H & B & W_0 & \overset{\Lambda}{\rightarrow} & U & (Y, Y^*) \\
\text{H} & B^* & W_0^* & \overset{\Lambda^*}{\leftarrow} & U \\
\end{array}
\]

**Basic problem.** Find \( p \in H \) and \( u \in \mathcal{V}_0 \) that satisfy the relation

\[
(\mathcal{A}\Lambda u, \Lambda w) + \langle f - B^* p, w \rangle = 0 \quad \forall w \in W_0,
\]

where

\[
\mathcal{V}_0 = \text{Ker}B := \{ v \in W_0 \mid Bv = 0 \}.
\]
Assume that
\[ \nu_1 \|y\|^2 \leq (Ay, y) \leq \nu_2 \|y\|^2, \quad y \in U, \]

Let the operator $B$ possesses the following property: there exists a constant $\alpha$ such that for any
\[ g \in \text{Im } B := \{z \in H \mid \exists v \in W_0 : Bv = z\} \]

one can find $u_g \in W_0$ such that
\[ Bu_g = g \quad \text{and} \quad \|u_g\|_W \leq \alpha \|g\|. \]

Note that such a condition is a generalization of Lemma 2.
Under the above assumption we obtain an estimate of the deviation from $u$. 
Estimate of the deviation from $u$

\[ \| \Lambda (u - \hat{v}) \| \leq \]

\[ \leq 2 \sqrt{\nu} \alpha \| B \hat{v} \| + \| \mathcal{A} \Lambda \hat{v} - y \|_* + \frac{1}{\sqrt{\nu}} \| f + \Lambda^* y - B^* q \| . \]

where $\| y \| := (\mathcal{A} y, y)^{1/2}$, $\| y \|_* := (\mathcal{A}^{-1} y, y)^{1/2}$ We see that the terms of the estimate present errors in the basic relations

\[ \begin{cases} 
\langle \Lambda^* \sigma + f - B^* p, w \rangle = 0 & \forall w \in \mathbf{V}_0, \\
\sigma = \mathcal{A} \Lambda u, \\
Bv = 0. 
\end{cases} \]
For the Stokes problem $\Lambda v = \nabla v$, $A = \nu I$, where $I$ denotes the identity operator and $Bv = -\text{div}v$. It is easy to see that in this case $\nu_1 = \nu_2 = \nu$, 

$$\| A\Lambda \hat{v} - y \|_* = \frac{1}{\sqrt{\nu}} \| \nu \nabla v - y \|.$$ 

Since $\| A(u - \hat{v}) \| = \sqrt{\nu} \| A(u - \hat{v}) \|$, we find that the general estimate coincides with (262).
NONLINEAR MODELS IN THE THEORY OF FLUIDS
Bingham fluids

In these models

\[ W(\varepsilon) = \mu \left| \varepsilon^D \right|^2 + \sqrt{2K_*} \left| \varepsilon^D \right| = W_1(\varepsilon) + W_2(\varepsilon) \]  

(265)

Here \( W_1 \) is the Newtonian potential of a viscous fluid and \( W_2 \) is the plastic potential. By the Moreau–Rockafellar theorem we have

\[ \partial W(\varepsilon) = \partial W_1(\varepsilon) + \partial W_2(\varepsilon). \]  

(266)

If \( |\varepsilon^D| \neq 0 \) then the relation reads

\[ \partial W(\varepsilon) = 2\mu \varepsilon^D + \frac{\sqrt{2K_*}}{|\varepsilon^D|} \varepsilon^D. \]  

(267)
Let us define $\partial W(\varepsilon)$ for the case $|\varepsilon^D| = 0$. Evidently, $W_1(\varepsilon) = 0$. To find $\partial W_2$ we recall that by definition, $\tau \in \partial W_2(\varepsilon)$ iff

$$\sqrt{2}K_* \left| \varepsilon^D \right| - \sqrt{2}K_* \left| \varepsilon^D \right| \geq \tau : (\varepsilon^D).$$

Note that

$$\tau : (\varepsilon^D) = \frac{1}{n} \text{tr} \; \tau \; (\text{tr} \; \varepsilon - \text{tr} \; \varepsilon) + \tau^D : \varepsilon^D,$$

Therefore,

$$\sqrt{2}K_* \left| \varepsilon^D \right| \geq \frac{1}{n} \text{tr} \; \tau \; (\text{tr} \; \varepsilon - \text{tr} \; \varepsilon) + \tau^D : \varepsilon^D \quad \forall \varepsilon^D.$$
Let $|\varepsilon^D| = 0$, then

$$0 \geq \frac{1}{n} \text{tr} \tau (\text{tr} \varepsilon - \text{tr} \varepsilon).$$

From here, it follows that

$$\text{tr}\tau = 0.$$

Therefore,

$$\sqrt{2K_*} \left| \varepsilon^D \right| \geq \tau^D : \varepsilon^D \quad \forall \varepsilon^D.$$

Without a loss of generality we may assume that $|\varepsilon^D| = 1$. To maximize the right–hand side we take $\varepsilon^D := \frac{\tau^D}{|\tau^D|}$. Then, we observe that

$$\sqrt{2K_*} \geq \left| \tau^D \right|.$$
Hence, \( \partial W_2(\varepsilon) \) for \( |\varepsilon^D| = 0 \) consists of all \( \tau \) such that \( \tau = \tau^D \) and

\[
|\tau^D| \leq \sqrt{2}K_*.
\]

(268)

This relation reflects the physical nature of a **viscoplastic fluid**. In the stagnation zone the deviatoric part of its stress is not uniquely defined and can be any provides (268) is satisfied. Later we will see the examples exposing such a behavior of a solution.
Bingham flow in a basin

We consider a flow problem in a fixed domain, i.e., $\Omega_t = \Omega$ and the "no–slip" conditions $u = u_0$ are imposed on the boundary. *Classical solution* is defined as $(u, \sigma, p)$ such that

\begin{align}
  u &\in C(\overline{\Omega}; \mathbb{R}^d) \cap W^1_2(\Omega; \mathbb{R}^d), \\
  \sigma &\in C(\overline{\Omega}; M^{n\times n}_s) \cap W^1_2(\Omega; M^{n\times n}_s), \\
  p &\in C(\Omega), \\
  \frac{\partial u}{\partial t} &\in L^2(\Omega; \mathbb{R}^d), \\
  f &\in L^2(\Omega; \mathbb{R}^d),
\end{align}

Consider Dirichlet boundary conditions.
Let $v \in H^1(\Omega; \mathbb{R}^d) = \{ v \in H^1(\Omega; \mathbb{R}^d) \mid v = 0 \text{ on } \partial \Omega \}$. Multiply
\[
\frac{\partial u}{\partial t} + u_i \frac{\partial u}{\partial x_i} - \text{div } \sigma = f
\]
by $v$ and integrate by parts.
\[
\int_{\Omega} \left( \frac{\partial u}{\partial t} \cdot v + u_i \frac{\partial u}{\partial x_i} \cdot v - v \text{div } \sigma \right) \, dx = \int_{\Omega} f v \, dx,
\]
\[
\int_{\Omega} \left( \frac{\partial u}{\partial t} + \frac{\partial u}{\partial x_i} \right) \cdot v \, dx + \int_{\Omega} \sigma : \varepsilon(v) \, dx = \int_{\Omega} f v \, dx.
\]
This relation may be rewritten as
\[
\int_{\Omega} \left( \frac{\partial u}{\partial t} + u_i \frac{\partial u}{\partial x_i} \right) \cdot v \, dx + \int_{\Omega} (\sigma + pI) : \varepsilon(v) \, dx = \int_{\Omega} (fv + p \text{div } v) \, dx \quad \forall v \in H^1(\Omega; \mathbb{R}^d)
\]
By the constitutive relations,

\[ \sigma + pl = \partial W_1 + \partial W_2 = 2\mu \varepsilon^D(u) + \partial W_2(\varepsilon(u)) \]

what means that

\[ \sigma + pl - 2\mu \varepsilon^D(u) \in \partial W_2(\varepsilon(u)) \]

The latter means that

\[ \sqrt{2k_*} \| \varepsilon^D \|_D - \sqrt{2k_*} \| \varepsilon^D(u) \|_D \geq \]

\[ \geq (\sigma + pl - 2\mu \varepsilon^D(u)) : (\varepsilon - \varepsilon(u)) \quad \forall \varepsilon \in M_{s \times n} \]
Set \( \varepsilon = \varepsilon(u + v) \). Then,

\[
\sqrt{2k_*} \left| \varepsilon^D \right| - \sqrt{2k_*} \left| \varepsilon^D(u) \right| \geq (\sigma + pl - 2\mu \varepsilon^D(u)) : \varepsilon(v).
\]

and we obtain

\[
\int_{\Omega} (\sigma + pl) : \varepsilon(v) \, dx \leq \int_{\Omega} (2\mu \varepsilon^D(u) : \varepsilon^D(v) + \sqrt{2k_*} \left| \varepsilon^D \right| - \sqrt{2k_*} \left| \varepsilon^D(u) \right| ) \, dx.
\]

Now (274) yields inequality

\[
\int_{\Omega} \left( \frac{\partial u}{\partial t} + u_i \frac{\partial u}{\partial x_i} \right) \cdot v \, dx + \int_{\Omega} (2\mu \varepsilon^D(u) : \varepsilon^D(v) + \sqrt{2k_*} \left| \varepsilon^D \right| - \sqrt{2k_*} \left| \varepsilon^D(u) \right| ) \, dx \geq \int_{\Omega} (fv + p \text{div} v) dx, \quad \forall v \in H^1(\Omega; \mathbb{R}^d).
\]
If a trial function is taken from a narrower set
\[ v = w + u_0 - u \quad , \quad w, u_0 \in J_2^1(\Omega) \]
so that
\[ \text{div} \ v = 0, \quad \varepsilon = \varepsilon(w + u_0) \]
Then (275) comes in a simpler form
\[
\int_{\Omega} \left\{ \left( \frac{\partial u}{\partial t} + u_i \frac{\partial u}{\partial x_i} \right) \cdot (w + u_0 - u) + 2\mu \varepsilon^D(u) : \varepsilon^D(w + u_0 - u) + \right. \\
+ \sqrt{2k_\star} \left( |\varepsilon^D(w + u_0)| - |\varepsilon^D(u)| \right) \right\} \, dx \geq \int_{\Omega} f \cdot (w + u_0 - u) \, dx \quad \forall w \in J_2^1(\Omega).
\]
Denote \( \tilde{u} = u_0 + w \), then we arrive at the variational inequality that describes the motion of an elastoplastic media

\[
\int_{\Omega} \left\{ \left( \frac{\partial u}{\partial t} + u_i \frac{\partial u}{\partial x_i} \right) \cdot (\tilde{u} - u) + 2\mu \varepsilon^D(u) : \varepsilon^D(\tilde{u} - u) + \sqrt{2}k_* \left( \left| \varepsilon^D(\tilde{u}) \right| - \left| \varepsilon^D(u) \right| \right) \right\} \, dx \geq \\
\geq \int_{\Omega} f \cdot (\tilde{u} - u) \, dx \\
\forall \tilde{u} \in u_0 + J_2^1(\Omega) \quad (276)
\]
Stationary model is a particular case of the above that arises if $\partial u / \partial t = 0$. Here, we need to find $u \in J^{1/2}(\Omega) + u_0$ such that

$$
\int_{\Omega} \left\{ u_i \frac{\partial u}{\partial x_i} \cdot (v - u) + 2\mu \varepsilon(u) : \varepsilon(v - u) + \sqrt{2k_\ast}(|\varepsilon(v)| - |\varepsilon(u)|) \right\} \ dx \geq \int_{\Omega} f \cdot (v - u) \ dx \ \forall v \in J^{1/2}(\Omega) + u_0. \quad (277)
$$

If, in addition, $v$ is small (slow flows) then we arrive at the problem

$$
\int_{\Omega} \left\{ 2\mu \varepsilon(u) : \varepsilon(v - u) + \sqrt{2k_\ast}(|\varepsilon(v)| - |\varepsilon(u)|) \right\} \ dx \geq \int_{\Omega} f \cdot (v - u) \ dx \quad \forall v \in J^{1/2}(\Omega) + u_0 \quad (278)
$$
Existence and uniqueness

Consider the problem: find \( u \in J^\frac{1}{2}(\Omega) + u_0 \) such that

\[
\int_{\Omega} 2\mu \varepsilon(u) \cdot \varepsilon(v - u) + \sqrt{2}K^*(|\varepsilon(v)| - |\varepsilon(u)|)dx \geq \int_{\Omega} f \cdot (v - u)dx \quad \forall v \in J^\frac{1}{2}(\Omega) + u_0, \quad (279)
\]

where \( f \in L^2(\Omega, \mathbb{R}^d), \ u_0 \in J^\frac{1}{2}(\Omega) \).

Uniqueness of the solution is easy to prove.
Regularity of weak solutions

Regularity of weak solutions in the theory of Non Newtonian viscous fluids was investigated in the works of M. Fuchs, G. Seregin, M. Bildhauer and other authors. Readers can find a consequent exposition of these results in the book

Let \( u_1, u_2 \in H^{1}(\Omega) + u_0 \) be two different solutions. Then

\[
\int_{\Omega} \left\{ \mu \varepsilon(u_1) \cdot \varepsilon(v - u_1) + \sqrt{2K_*} (|\varepsilon(v)| - |\varepsilon(u_1)|) - f \cdot (v - u_1) \right\} dx \geq 0
\]

\[
\int_{\Omega} \left\{ \mu \varepsilon(u_2) \cdot \varepsilon(v - u_2) + \sqrt{2K_*} (|\varepsilon(v)| - |\varepsilon(u_2)|) - f \cdot (v - u_2) \right\} dx \geq 0
\]

Set \( v = u_2 \) in the first and \( v = u_1 \) in the second.

\[
\int_{\Omega} \mu \varepsilon(u_1 - u_2) \cdot \varepsilon(u_2 - u_1) dx \geq 0
\]

Thus,

\[
\int_{\Omega} |\varepsilon(u_1 - u_2)|^2 dx \leq 0
\]
Existence

Existence follows from that the problem is equivalent to the variational problem

\[ I(u) = \inf \{ I(v) : v \in \mathcal{J}_2^1(\Omega) + u_0 \}, \]  

(280)

where

\[ I(v) = \int_{\Omega} \{ \mu |\varepsilon(u)|^2 + \sqrt{2K_*} |\varepsilon(v)| - f \cdot v \} \, dx \]

This equivalence follow from the well known result (see, e.g., J.-L. Lions and G. Duvaut. Enequalities in mechanics and physics).
Theorem

Variational problem

\[
\inf_{v \in K} J(v) = J(v^*); \quad J(v) = J_0(v) + j(v), \tag{281}
\]

where \( K \) is a convex closed set, \( J_0 : V \to \mathbb{R} \) is a convex differentiable functional, \( j : V \to \mathbb{R} \) is a convex functional, \( V \) has the same solution as the variational inequality

\[
(J'_0(v^*), v^* - v) + j(v^*) - j(v) \leq 0, \quad \forall v \in K \tag{282}
\]
In our case

\[ J_0(v) = \int_{\Omega} \mu |\varepsilon(u)|^2 \, dx - \int_{\Omega} f \cdot v \, dx \]

\[ j(v) = \sqrt{2} K_* \int_{\Omega} |\varepsilon(u)| \, dx \]

\[ K = J_2^1(\Omega) + u_0, \quad V = H^1(\Omega, \mathbb{R}^n) \]

and we arrive at

\[ I(v) = \int_{\Omega} \left\{ \mu |\varepsilon(u)|^2 + \sqrt{2} K_* |\varepsilon(v)| - f \cdot v \right\} \, dx \]

which is convex, continuous, and coercive. These properties imply existence.
Approximate solutions

Let $V_h \subset J^1_2(\Omega)$ and $\dim V_h < +\infty$, find $u_h \in V_h + u_0$,

\[
\int_{\Omega} \mu \varepsilon(u_h) \cdot (\varepsilon(v_h) - \varepsilon(u_h)) \, dx + \int_{\Omega} \sqrt{2}K_* (|\varepsilon(v_h)| - |\varepsilon(u_h)|) \, dx \geq \int_{\Omega} f \cdot (v_h - u_h) \, dx
\]

$\forall v_h \in V_h + u_0$ (283)

Variational formulation: find $u_h \in V_h + u_0$ such that

\[
I(u_h) = \inf \{ I(v_h) : v_h \in V_h + u_0 \}
\]

(284)

Serious difficulty is the condition

$$\text{div } v_h = 0.$$
Example. Antiplane flow in a pipe

Consider a long tube of the cross-section $\Omega$ with the income and outcome pressure:

$$p(x_1, x_2, 0, t) = 0, \quad p(x_1, x_2, L, t) = -cL$$

(285)

On the side surface

$$u \mid_{\partial\Omega \times [0,L]} = 0,$$

(286)

We are looking for a solution of the form

$$u_1 = 0, \quad u_2 = 0, \quad u_3 = w(x_1, x_2, t)$$

$$\varepsilon(u) = \begin{pmatrix} 0 & 0 & 1 \frac{1}{2}w_1 \\ 0 & 0 & 1 \frac{1}{2}w_2 \\ 1 \frac{1}{2}w_1 & 1 \frac{1}{2}w_2 & 0 \end{pmatrix}$$
Since

\[
\varepsilon(u) = \begin{pmatrix} 0 & 0 & \frac{1}{2} \mathbf{w},1 \\ 0 & 0 & \frac{1}{2} \mathbf{w},2 \\ \frac{1}{2} \mathbf{w},1 & \frac{1}{2} \mathbf{w},2 & 0 \end{pmatrix}
\]

we have

\[
|\varepsilon(u)|^2 = \frac{1}{2} |\nabla \mathbf{w}|^2, \quad \frac{\partial \mathbf{u}}{\partial x_1} = (0, 0, \mathbf{w},1), \quad \frac{\partial \mathbf{u}}{\partial x_2} = (0, 0, \mathbf{w},2), \quad \frac{\partial \mathbf{u}}{\partial x_3} = (0, 0, 0), \quad \mathbf{u}_i \frac{\partial \mathbf{u}}{\partial x_i} = 0
\]

\[
\mathbf{u}_i \frac{\partial \mathbf{u}}{\partial x_i} = 0, \quad \text{div} \mathbf{u} = 0 \quad (287)
\]
Remark

If set in \((277)\) \(v = (0, 0, \tilde{w})\), where \(\tilde{w} \in H^1(\Omega)\), \(\tilde{w} = \tilde{w}(x_1, x_2)\), \(u_0 = 0\) and \(f = (0, 0, c)\), then we arrive at the problem

\[
\int_{\Omega} \left\{ \mu \nabla w \cdot (\nabla \tilde{w} - \nabla w) + k_* (|\nabla \tilde{w}| - |\nabla w|) \right\} \, dx \geq \\
\geq \int_{\Omega} c(\tilde{w} - w) \, dx \quad \forall \tilde{w} \in H^1(\Omega).
\]

We see that stationary slow flow of a viscoplastic fluid in a pipe is described by a **variational inequality**.
In this case,

\[ \sigma + p l = \tau = \begin{pmatrix} 0 & 0 & \tau_{31}(x_1, x_2, t) \\ 0 & 0 & \tau_{32}(x_1, x_2, t) \\ \tau_{31}(x_1, x_2, t) & \tau_{32}(x_1, x_2, t) & 0 \end{pmatrix} \]

and \( \tau = \tau^D \).

Let \( \rho_0 = 1 \). Take the third equation of the motion:

\[ \frac{\partial w}{\partial t} = \sigma_{31,1} + \sigma_{32,2} + \sigma_{33,3}, \quad (288) \]

Here \( \sigma = \tau - pl \) and \( \sigma_{33} = -p \).
Therefore, we have

\[
\frac{\partial w}{\partial t} = \sigma_{31,1} + \sigma_{32,2} - \frac{\partial p}{\partial x_3}
\]  

(289)

Since \( \sigma_{31}, \sigma_{32}, \) and \( w \) depend only on \( x_1, x_2 \), we rewrite \( 289 \) as follows:

\[
\frac{\partial p}{\partial x_3} = a(x_1, x_2, t)
\]

Thus,

\[
p(x_1, x_2, x_3, t) = a(x_1, x_2, t) + x_3 b(x_1, x_2, t).
\]

Boundary conditions \( (285) \) say that

\[
p(x_1, x_2, 0, t) = a(x_1, x_2, t) = 0,
\]

\[
p(x_1, x_2, L, t) = Lb(x_1, x_2, t) = -cL \implies b = -c.
\]

Hence, the pressure is found as \( p = -C x_3 \).
Now the motion is governed by the single equation

\[
\frac{\partial \mathbf{w}}{\partial t} = \frac{\partial \sigma_{31}}{\partial x_1} + \frac{\partial \sigma_{32}}{\partial x_2} + \mathbf{c}
\]  

(290)

Recall that

\[
| \varepsilon(u) |^2 = \frac{1}{2} | \nabla \mathbf{w} |^2
\]

Rewrite the constitutive relation

\[
\sigma + \mathbf{p} \mathbf{l} = \begin{cases} 
2 \mu \varepsilon(u) + \sqrt{2} K_* \frac{\varepsilon(u)}{| \varepsilon(u) |} & \text{for } | \varepsilon(u) | > 0 \\
\tau = \tau^D, | \tau^D | \leq \sqrt{2} K_* & \text{for } | \varepsilon(u) | = 0
\end{cases}
\]

in terms of the problem considered.
We have

\[ \sigma_{3i} = \begin{cases} 
(2\mu + \sqrt{2}K_* \frac{1}{\sqrt{2} |\nabla w|}) \frac{1}{2} w_i, & \text{for } |\nabla w| > 0, \\
\tau_{3i}, & \text{for } |\nabla w| = 0,
\end{cases} \quad i = 1, 2. \]  

(291)

where \( |\tau^D|^2 = 2\tau_{31}^2 + 2\tau_{32}^2 \). Therefore,

\[ \sigma_{3i} = \begin{cases} 
(\mu + \frac{K_*}{|\nabla w|}) w_i, & \text{for } |\nabla w| > 0, \\
\tau_{3i}, \quad \sqrt{\tau_{31}^2 + \tau_{32}^2} \leq K_*, & \text{for } |\nabla w| = 0.
\end{cases} \]  

(292)
We observe that

\[ |\sigma_3| := \sqrt{(\sigma_{31}^2 + \sigma_{32}^2)} = \begin{cases} \mu \ |\nabla w| + K_*, & \text{for } |\nabla w| > 0, \\ \sqrt{\tau_{31}^2 + \tau_{32}^2} \leq K_*, & \text{for } |\nabla w| = 0 \end{cases}. \]

Now (292), the equation

\[ \frac{\partial w}{\partial t} = \text{div}\sigma_3 + c. \]

and the condition

\[ w |_{\partial\Omega} = 0 \]

(293)

describes the solution.
Cylindrical pipe

Consider stationary flow in a cylindrical pipe.

\[ \sigma_3 := \eta = (\eta_\rho, \eta_\varphi), \quad \eta_\rho = \sigma_{3\rho}, \quad \eta_\varphi = \sigma_{3\varphi}. \]

Problem is axisymmetric and

\[ \sigma_{3\varphi} = 0, \quad \frac{\partial \mathbf{w}}{\partial \varphi} = 0. \]

Problem is stationary:

\[ \frac{\partial \mathbf{w}}{\partial t} = 0. \]

In the axisymmetric case

\[ \text{div}(\sigma_3) = \text{div} \eta = \frac{\partial \eta_\rho}{\partial \rho} + \frac{\eta_\rho}{\rho}, \]
Now, the motion equation reads

$$\frac{\partial \eta_\rho}{\partial \rho} + \frac{\eta_\rho}{\rho} + c = 0 \quad \Rightarrow \quad \frac{1}{\rho} \frac{\partial (\rho \eta_\rho)}{\partial \rho} + c = 0 \quad (294)$$

$$\eta_\rho = \left\{ \begin{array}{l}
\left( \mu + \frac{K_\ast}{\partial w} \right) \frac{\partial w}{\partial \rho} \quad \text{for} \quad |\frac{\partial w}{\partial \rho}| > 0, \\
|\frac{\partial w}{\partial \rho}| \quad .
\end{array} \right. \quad (295)$$

$$\tilde{\eta}_\rho, |\tilde{\eta}_\rho| \leq K_\ast \quad \text{for} \quad |\frac{\partial w}{\partial \rho}| = 0$$
From the viewpoint of physics it would be natural to await the following behavior of the media:

1. If the "pressure grade" $c$ is small, then there is no motion at all: plastic properties of the media dominate and does not allow any motion.

2. If $c$ becomes large enough, then the motion starts in places where the effective stresses achieve the critical value, i.e. near the boundary. Central part moves as a solid body.
Formal analysis confirms these expectations. Integrate (294), then we observe that

\[
\eta_\rho = -\frac{c}{2}\rho + \frac{C_2}{\rho}
\]  \hspace{1cm} (296)

\(\sigma_{3\rho}\) at the center must be finite, therefore \(C_2 = 0\) and (296) reads

\[
\eta_\rho = -\frac{c}{2}\rho
\]  \hspace{1cm} (297)

For which \(c\) no motion arise?

\[
|\eta_\rho(\rho)| \leq |\eta_\rho(R)| = \frac{c}{2}R \leq K_*,
\]

Hence, these values are: \(c \leq \frac{2K_*}{R}\).
Indeed, in such a case we have a function $\eta_\rho$ that satisfies the equation and constitutive relations related to the branch $|\frac{\partial w}{\partial \rho}| = 0$. Since $w|_{\partial \Omega} = 0$ we conclude that $w \equiv 0$. Let $c > \frac{2K^*_R}{R}$. We are looking for a solution such that

1. for $R^*_R \leq \rho \leq R$ the media is deformed and $|\frac{\partial w}{\partial \rho}| > 0$

2. for $0 \leq \rho \leq R^*_R$ the media is rigid and $|\frac{\partial w}{\partial \rho}| = 0$. 
Then $\mathbf{R}_*$ is defined by the relation

$$| \eta_\rho(\mathbf{R}_*) | = \frac{c}{2} \mathbf{R}_* = K_* \implies \mathbf{R}_* = \frac{2K_*}{c} < R$$

For $\mathbf{R}_* \leq \rho \leq \mathbf{R}$ it should be $\frac{\partial w}{\partial \rho} < 0$, so that

$$\eta_\rho = \left( \mu + \frac{K_*}{| \frac{\partial w}{\partial \rho} |} \right) \frac{dw}{d\rho} = \mu \frac{dw}{d\rho} - K_*.$$

The latter relation leads to the conclusion that

$$\mu \frac{dw}{d\rho} - K_* = -\frac{c}{2} \rho \implies \mu w - K_* \rho = -\frac{c}{4} \rho^2 + C_3$$

$$0 = K_* R - \frac{c}{4} R^2 + C_3 \implies C_3 = \frac{c}{4} R^2 - K_* R. \quad (298)$$

Consequently $\mu w = K_*(\rho - R) - \frac{c}{4}(\rho^2 - R^2)$. 
Therefore, we arrive at the conclusion that for $c > \frac{2K_*}{R}$ the solution is as follows:

$$w = \begin{cases} 
\frac{1}{\mu} \left[ (R_* - R) - \frac{c}{4} (R_*^2 - R^2) \right] & 0 \leq \rho \leq R_* , \\
\frac{1}{\mu} \left[ (\rho - R) - \frac{c}{4} (\rho^2 - R^2) \right] & R_* \leq \rho \leq R .
\end{cases}$$

Thus,

$$\frac{dw}{d\rho} = 0 \quad \text{for} \quad 0 \leq \rho \leq R_*$$

and

$$\frac{1}{\mu} \left[ 1 - \frac{c}{2} \rho \right] \quad \text{for} \quad R_* \leq \rho \leq R .$$
FUNCTIONAL A POSTERIORI ESTIMATES FOR GENERALIZED NEWTONIAN FLUIDS
For the considered class of problems it is convenient to derive estimates of deviations from exact solutions by the variational method. First, we establish the estimate

\[ \frac{\nu}{2} \int_{\Omega} |\varepsilon(v - u)|^2 \, dx \leq J(v) - J(u), \tag{299} \]

where \( v \) is an arbitrary function in \( \overset{\circ}{H}^1_0(\Omega) + u_0 \). Indeed,

\[ J(v) - J(u) = \int_{\Omega} \left( \frac{\nu}{2} |\varepsilon(v - u)|^2 + \nu \varepsilon(u) : \varepsilon(v - u) + \sqrt{2}K_*(|\varepsilon(v)| - |\varepsilon(u)|) \right) dx - \int_{\Omega} f \cdot (v - u) \, dx. \]
To estimate \( J(u) \) from below, we construct a set of variational problems whose functionals are defined on the functional class wider than \( J^1_2(\Omega) + u_0 \). These problems we shall call "disturbed".

Let us define two functions \( q \in L^2_2(\Omega) \) and \( \tau_2 \in \Sigma \) and the functional

\[
\bar{J}(v) := \int_{\Omega} \left( \frac{\nu}{2} |\varepsilon(v)|^2 + \tau_2 : \varepsilon(v) - \psi^*(\tau_2) - f \cdot v - q \text{div}(v - u_0) \right) \, dx,
\]

where \( \psi^* : \mathbb{M}^{d \times d} \rightarrow \mathbb{R} \) is the functional conjugate to \( \psi(\kappa) := \sqrt{2} K_\star |\kappa| \) in the sense of Young–Fenchel, i.e.,

\[
\psi^*(\kappa^*) = \sup_{\kappa \in \mathbb{M}^{d \times d}} \{ \kappa^* : \kappa - \psi(\kappa) \}.
\]
Now, the following variational problem $\bar{\mathcal{P}}_{q,\tau_2}$ arises: Find $\bar{u} \in V_0 + u_0$ such that

$$\bar{J}(\bar{u}) = \inf \bar{\mathcal{P}} := \inf_{v \in V_0 + u_0} \bar{J}(v).$$

Here, in principle, $\bar{u} = \bar{u}_{q,\tau_2}$. However, for the sake of simplicity we shall not do this assuming that the bar above means that a quantity depends on the above functions.

Problem $\bar{\mathcal{P}}$ is uniquely solvable and

$$\inf \bar{\mathcal{P}} \leq \inf \mathcal{P}. \quad (300)$$
Existence and uniqueness of $\bar{u}$ follows from the properties of the convex functional $\bar{J}$ and closed set $V_0 + u_0$. In accordance with the definition of $\psi^*$, for any $v \in J^1_2(\Omega) + u_0$ we have the inequality

$$
\bar{J}(v) = \int_\Omega \left( \frac{\nu}{2} |\varepsilon(v)|^2 + \tau_2 : \varepsilon(v) - \psi^*(\tau_2) \right) \, dx - \int_\Omega f \cdot v \, dx \leq J(v).
$$

Therefore,

$$
\inf_{v \in V_0 + u_0} \bar{J}(v) \leq \inf_{v \in J^1_2(\Omega) + u_0} \bar{J}(v) \leq \inf_{v \in J^1_2(\Omega) + u_0} J(v) = \inf \mathcal{P}.
$$
Now, we observe that

\[ \frac{\nu}{2} \int_{\Omega} |\varepsilon(v - u)|^2 \, dx \leq J(v) - \inf \bar{P}. \]  

(301)

However, the value of \( \inf \bar{P} \) is unknown! To overcome this difficulty we attract dual variational problem \( \bar{P}^* \). If \( \inf \bar{P} = \sup \bar{P}^* \), then \( \inf \bar{P} \) can be replaced by a lower estimate of \( \sup \bar{P}^* \). Estimates obtained on this way will depend on the functions \( \tau_2 \) and \( q \) and also on the variables of the dual problem. Note that there are different variational problem that may be viewed as dual to \( \bar{P} \). The problem is to find in this collection a proper variant that leads to estimates convenient for practice and having a good accuracy. For the class of problems considered, the following variant is possible.
Define the Lagrangian

\[ \bar{L}(v; \tau_1) := \int_{\Omega} \left( \varepsilon(v) : (\tau_1 + \tau_2) - \frac{1}{2\nu} |\tau_1|^2 - \psi^*(\tau_2) \right) dx \]

\[ - \int_{\Omega} f \cdot v dx - \int_{\Omega} q \cdot \text{div} \cdot (v - u_0) dx. \]

Then,

\[ \bar{J}(v) = \sup_{\tau_1 \in \Sigma} \bar{L}(v; \tau_1), \]

so that Problem \( \bar{\mathcal{P}} \) is equivalent to the minimax problem

\[ \inf_{v \in V_0 + u_0} \sup_{\tau_1 \in \Sigma} \bar{L}(v; \tau_1). \]

The respective dual problem is

\[ \sup_{\tau_1 \in \Sigma} \inf_{v \in V_0 + u_0} \bar{L}(v; \tau_1). \]
Note that

\[
\inf_{v \in V_0 + u_0} \bar{L}(v; \tau_1) = \begin{cases} 
\bar{I}(\tau_1) & \text{if } \tau_1 \in \tilde{\Sigma}_f(\Omega), \\
-\infty & \text{if } \tau_1 \not\in \tilde{\Sigma}_f(\Omega), 
\end{cases}
\]

where

\[
\bar{I}(\tau_1) = \int_{\Omega} \left( \varepsilon(u_0) : (\tau_1 + \tau_2) - \frac{1}{2\nu} |\tau_1|^2 - \psi^*(\tau_2) - f \cdot u_0 \right) dx,
\]

and \( \tilde{\Sigma}_f \) is an affine subset in \( \Sigma \) that consists of the functions \( \tau \) satisfying (in a generalized sense) the condition \( \text{div}(\tau + \tau_2) = \nabla q - f \), i.e.,

\[
\tilde{\Sigma}_f(\Omega) := \left\{ \tau \in \Sigma(\Omega) \left| \int_{\Omega} \varepsilon(w) : (\tau + \tau_2) \, dx \right. \right\} 
\]

\[
= \int_{\Omega} (f \cdot w + q \text{div } w) \, dx, \quad w \in V_0.
\]
Thus, we arrive at the following formulation of the Dual Variational Problem.

**Problem \( \bar{P}^* \)** For given \( \tau_2 \in \Sigma \) and \( q \in L_2(\Omega) \) find a function \( \bar{\sigma}_1 \in \bar{\Sigma}_f(\Omega) \) such that

\[
\bar{I}(\bar{\sigma}_1) = \sup \bar{P}^* := \sup_{\tau_1 \in \bar{\Sigma}_f} \bar{I}(\tau_1).
\]
Theorem

Problem $\tilde{P}^*$ has a unique solution $\tilde{\sigma}_1$ satisfying the conditions

$$\inf \tilde{P} = \tilde{J}(\tilde{u}) = \sup \tilde{P}^* = \tilde{I}(\tilde{\sigma}_1),$$

$$\nu \varepsilon(\tilde{u}) = \tilde{\sigma}_1.$$
Proof.

$-\overline{I}$ is strictly convex and $\overline{\Sigma_f}$ is a convex and closed subset of $\Sigma$. Therefore, Problem $\overline{P}^*$ has a unique solution.

Note that $\sup \overline{P}^* \leq \inf \overline{P}$. This fact follows from the relation

$$\sup \inf \overline{L} \leq \inf \sup \overline{L}$$

$\overline{u}$ satisfies the integral identity

$$\int_{\Omega} (\nu \varepsilon(\overline{u}) : \varepsilon(w) + \tau_2 : \varepsilon(w)) \, dx = \int_{\Omega} (f \cdot w + q \text{div} w) \, dx \quad w \in V_0.$$ 

From here, it follows that

$$\int_{\Omega} f \cdot \overline{u} \, dx = \int_{\Omega} (\nu |\varepsilon(\overline{u})|^2 - \nu \varepsilon(\overline{u}) : \varepsilon(u_0) +$$

$$+ \tau_2 : \varepsilon(\overline{u} - u_0) + f \cdot u_0 - q \text{div}(\overline{u} - u_0)) \, dx.$$
Therefore,

\[
\inf \bar{P} = \bar{J}(\bar{u}) \\
= \int_\Omega \left( \frac{\nu}{2} |\varepsilon(\bar{u})|^2 + \tau_2 : \varepsilon(\bar{u}) - \psi^*(\tau_2) \right) \, dx - \int_\Omega (q \text{div}(\bar{u} - u_0) + f \cdot \bar{u}) \, dx \\
= \int_\Omega \left( \tau_2 : \varepsilon(u_0) - \frac{\nu}{2} |\varepsilon(\bar{u})|^2 - \psi^*(\tau_2) + \nu \varepsilon(u_0) : \varepsilon(\bar{u}) \right) \, dx - \int_\Omega f \cdot u_0 \, dx.
\]

Since \( \nu \varepsilon(\bar{u}) \in \bar{\Sigma}_f \), we know that

\[
\bar{I}(\nu \varepsilon(\bar{u})) \leq \sup \bar{P}^*
\]
\[ \bar{I}(\nu \varepsilon(\bar{u})) = \]
\[ = \int_\Omega \left( \varepsilon(u_0) : (\nu \varepsilon(\bar{u}) + \tau_2) - \frac{\nu}{2} |\varepsilon(\bar{u})|^2 - \psi^*(\tau_2) \right) \, dx - \int_\Omega f \cdot u_0 \, dx \leq \]
\[ \leq \sup \bar{P}^* \leq \inf \bar{P} = \]
\[ = \int_\Omega \left( \tau_2 : \varepsilon(u_0) - \frac{\nu}{2} |\varepsilon(\bar{u})|^2 - \psi^*(\tau_2) + \nu \varepsilon(u_0) : \varepsilon(\bar{u}) \right) \, dx - \int_\Omega f \cdot u_0 \, dx. \]

Consequently, \( \nu \varepsilon(\bar{u}) = \sigma_1 \) and
\[ \inf \bar{P} = \sup \bar{P}^*. \]
Estimates of deviations from exact solutions for solenoidal fields

Let \( \mathbf{v} \in \mathcal{J}^{1}_{2}(\Omega) + \mathbf{u}_0 \). For it and \( \tau_{1f} \in \mathcal{S}_f(\Omega) \) the inequality

\[
\int_{\Omega} \frac{\nu}{2} |\varepsilon(\mathbf{v} - \mathbf{u})|^2 \, dx \leq (304)
\]

\[
\leq J(\mathbf{v}) - \inf \bar{\mathcal{P}} = J(\mathbf{v}) - \sup \bar{\mathcal{P}}^* \leq J(\mathbf{v}) - \bar{I}(\tau_{1f})
\]

holds. Estimate the right-hand side of (304) as follows:

\[
J(\bar{\mathbf{v}}) - \bar{I}(\tau_{1f}) \leq \int_{\Omega} \left( \frac{\nu}{2} |\varepsilon(\mathbf{v})|^2 + \frac{1}{2\nu} |\tau_{1f}|^2 - \varepsilon(\mathbf{u}_0) : \tau_{1f} \right) \, dx
\]

\[
+ \int_{\Omega} (\psi(\varepsilon(\mathbf{v})) + \psi^*(\tau_2) - \varepsilon(\mathbf{u}_0) : \tau_2) \, dx + \int_{\Omega} f \cdot (\mathbf{u}_0 - \mathbf{v}) \, dx.
\]
Let $q \in L^2(\Omega)$. Since $\tau_f \in \tilde{\Sigma}_f(\Omega)$ and $v \in J^1_2(\Omega) + u_0$, we have
\[
\int_{\Omega} f \cdot (u_0 - v) \, dx = \int_{\Omega} (f \cdot (u_0 - v) + q \text{div}(u_0 - v)) \, dx
\]
\[
= \int_{\Omega} \varepsilon(u_0 - v) : (\tau_f + \tau_2) \, dx.
\]
As a result, we obtain the following estimate:
\[
\frac{\nu}{2} \| \varepsilon(v - u) \|^2 \leq M_1(v, \tau_f, \tau_2) := D_1(\varepsilon(v), \tau_f) + D_2(\varepsilon(v), \tau_2), \quad (305)
\]
Here we have introduced \textit{compound functionals}

\[
D_1(\varepsilon(\mathbf{v}), \mathbf{\tau}_\mathbf{f}) := \int_{\Omega} \left( \frac{\nu}{2} |\varepsilon(\mathbf{v})|^2 + \frac{1}{2\nu} |\mathbf{\tau}_\mathbf{f}|^2 - \varepsilon(\mathbf{v}) : \mathbf{\tau}_\mathbf{f} \right) \, d\mathbf{x} = \\
= \frac{1}{2\nu} \| \nu \varepsilon(\mathbf{v}) - \mathbf{\tau}_\mathbf{f} \|^2;
\]

\[
D_2(\varepsilon(\mathbf{v}), \mathbf{\tau}_2) := \int_{\Omega} \left( \psi(\varepsilon(\mathbf{v})) + \psi^*(\mathbf{\tau}_2) - \varepsilon(\mathbf{v}) : \mathbf{\tau}_2 \right) \, d\mathbf{x}.
\]

It is clear that both functionals $D_1$ and $D_2$ are nonnegative. Moreover,

\[
D_1(\varepsilon(\mathbf{v}), \mathbf{\tau}_\mathbf{f}) = 0
\]

if and only if

\[
\mathbf{\tau}_\mathbf{f} = \nu \varepsilon(\mathbf{v}).
\]
By the properties of the conjugate functionals

\[ D_2(\varepsilon(v), \tau_2) = 0 \]

if and only if

\[ \tau_1 f \in \partial \psi(\varepsilon(v)). \]

Now, it is easy to understand the meaning of the estimates (305). Present the main system in the form

\[
\begin{align*}
-\text{div}(\sigma_1 + \sigma_2) &= f - \nabla p & \text{in } \Omega, \\
\text{div} u &= 0 & \text{in } \Omega, \\
\sigma_1 &= \nu \varepsilon(u), \sigma_2 \in \partial \psi(\varepsilon(u)) & \text{in } \Omega, \\
u &= u_0 & \text{on } \partial \Omega.
\end{align*}
\]
If \( \mathbf{v} \in \mathring{J}^{1}_2(\Omega) + \mathbf{u}_0 \), and \( \boldsymbol{\tau}_{\mathcal{I}_f} \in \bar{\Sigma}_f(\Omega) \), then

\[
-\text{div}(\boldsymbol{\tau}_{\mathcal{I}_f} + \boldsymbol{\tau}_2) = \mathbf{f} - \nabla \mathbf{q} \quad \text{and} \quad \text{div}\mathbf{v} = 0,
\]

so that for \( \mathbf{v}, \boldsymbol{\tau}_{\mathcal{I}_f}, \boldsymbol{\tau}_2 \) and \( \mathbf{q} \) the relations (306), (307) and (309) are satisfied.

Our estimate shows that in this case, the energy norm of the deviation from the exact solution is controlled by the quantities

\[
D_1(\varepsilon(\mathbf{v}), \boldsymbol{\tau}_{\mathcal{I}_f}) \quad \text{and} \quad D_2(\varepsilon(\mathbf{v}), \boldsymbol{\tau}_2),
\]
Certainly, the condition $\tau_{1f} \in \bar{\Sigma}_f(\Omega)$ is rather obligatory and it would be useful to somehow eliminate it. This can be done by the same method as we have discussed for linear problems. As a result, we obtain the estimate

$$
\frac{\nu}{2} \| \varepsilon(v-u) \|^2 \leq (1 + \beta) D_1(\varepsilon(v), \tau_1) + D_2(\varepsilon(v), \tau_2)
+ \frac{1 + \beta}{2\nu\beta} \| \text{div}(\tau_1 + \tau_2) + f - \nabla q \|^2,
$$

that holds for any function $v \in \mathcal{J}^1(\Omega) + u_0$, any pair of functions $(\tau_1, \tau_2) \in \Sigma \times \Sigma$, and any $\beta > 0$. The right-hand side of (310) is the majorant of the norm of the deviation from the exact solution that we denote by $\mathcal{M}_2(\beta, v, \tau_1, \tau_2, q)$. 

---

Mat-5.210 Special Course in Computational Mechanics, Autumn 2006, S. Repin

Helsinki University of Technology

A POSTERIORI ANALYSIS FOR PDE’s.
If the sum $\boldsymbol{\tau}_1 + \boldsymbol{\tau}_2$ has a higher regularity, so that

$$(\boldsymbol{\tau}_1 + \boldsymbol{\tau}_2) \in \Sigma_{\text{div}}(\Omega)$$

and, in addition, $q \in H^1$, then the last term of the Majorant is estimated by an explicitly computable integral:

$$\frac{\nu}{2} \| \varepsilon(v-u) \|^2 \leq (1 + \beta)D_1(\varepsilon(v), \tau_1) + D_2(\varepsilon(v), \tau_2) +$$

$$+ \frac{1 + \beta}{2\nu \beta} C_\Omega^2 \| \text{div} (\tau_1 + \tau_2) + f - \nabla q \|^2. \quad (311)$$
Theorem

For any $\beta \in \mathbb{R}_+$, $v \in J^1_2(\Omega) + u_0$, $\tau_1 \in \Sigma$, $\tau_2 \in \Sigma$ and $q \in L^2(\Omega)$ the functional $M_2(\beta, v, \tau_1, \tau_2, q)$ majorizes the quantity $\|\varepsilon(v - u)\|^2$.

For any $\beta \in \mathbb{R}_+$, infimum of this functional on the set

$$(J^1_2(\Omega) + u_0) \times \Sigma \times \Sigma \times L^2(\Omega)$$

is equal to zero and it is attained if and only if $v = u$, $\tau_1 = \sigma_1$, $\tau_2 = \sigma_2$ and $q = p$. 
Example 1.
For the Stokes problem $K_\ast = 0$, $\psi(\varepsilon) \equiv 0$. Set $\tau_2 = 0$. Then, $D_2(\varepsilon(v), \tau_2) \equiv 0$ and (310) comes in the form we have already obtained.

Example 2.
For the Bingham model $\psi(\varepsilon) = K_\ast |\varepsilon|$, and

$$
\psi^*(\tau(x)) = \begin{cases}
0, & \text{if } |\tau(x)| \leq K_\ast, \\
+\infty, & \text{if } |\tau(x)| > K_\ast.
\end{cases}
$$
Therefore,

\[ D_2(\varepsilon(v), \tau_2) = \int_{\Omega} (k_* | \varepsilon(v) | - \varepsilon(v) \cdot \tau_2) \, dx , \]

if almost everywhere the function \( \tau_2 \) satisfies the condition \( | \tau_2(x) | \leq K_* \).

In the opposite case, \( D_2(\varepsilon(v), \tau_2) = +\infty \). Then, (310) comes in the form:

\[
\frac{\nu}{2} \| \varepsilon(v - u) \|^2 \leq \int_{\Omega} \left( \frac{(1 + \beta)}{2\nu} | \nu \varepsilon(v) - \tau_1 |^2 + K_* | \varepsilon(v) | - \varepsilon(v) : \tau_2 \right) \, dx \\
+ \frac{1 + \beta}{2\beta \nu} \| \text{div} \( \tau_1 + \tau_2 \) + f - \nabla q \|^2 . \tag{312} \]

If the functions \( \tau_1, \tau_2 \) and \( q \) are taken such that \( q \in H^1 \)
\( \text{div} \( \tau_1 + \tau_2 \) \in L_2(\Omega) \), then the last term in (312) is estimated by the integral.
Bingham fluid may have too zones: the congestion zone $\Omega_0$ (where $\varepsilon(u) \equiv 0$) and the flow zone $\Omega_1$ (where $|\varepsilon(u)| > 0$).

Assume that the right–hand side of (312) vanishes for certain functions $v$, $\tau_1$, $\tau_2$ and $q$. Then, in $\Omega_0$ we have $\varepsilon(v) = 0$, and, consequently, $\tau_1 = 0$ and $\text{div}\tau_2 + f - \nabla q = 0$ for some $\tau_2$, satisfying the condition $|\tau_2(x)| \leq 1$.

At the same time, in the flow zone $\Omega_1$ the relations

$$\tau_2 = k_* \frac{\varepsilon(v)}{|\varepsilon(v)|}, \quad \tau_1 = \nu \varepsilon(v), \quad \text{div}(\tau_1 + \tau_2) + f - \nabla q = 0$$

hold.
GENERAL APPROACH TO A POSTERIORI ERROR CONTROL FOR NONLINEAR VARIATIONAL PROBLEMS
In subsequent lectures we will present the general theory of a posteriori error control for convex variational problems. In the framework of this theory we are able to derive computable upper bounds for the errors for problems of the type

$$\inf_{v \in V} J(v, \Lambda v), \quad J(v, \Lambda v) := G(\Lambda v) + F(v),$$

where $\Lambda : V \rightarrow Y$ is a linear continuous operator from a Banach space $V$ to another Banach space $Y$ and $J : Y \rightarrow \mathbb{R}$ and $F : V \rightarrow \mathbb{R}$ are convex l.s.c. functionals.
In particular, if

\[ \Lambda v = \nabla v, \quad G(y) = (Ay, y), \quad F(v) = (f, v), \]

then we arrive to the variational formulation of the problem

\[ \text{div} A \nabla u + f = 0. \]

Many other problems have the above form, were

G is the energy functional whose form is dictated by the dissipative properties of a media.
F is the functional associated with external forces and (or) boundary conditions.
Diffusion type problems,
Linear elasticity,
Biharmonic problems,
Kirghhoff and Mindlin plates,
Problems in deformation theory of elastoplasticity,
p-Laplace equation,
Stokes problem,
Nonlinear problems in the theory of viscous fluids and many other problems can be presented in the above general form.

In such models, the structure of the "energy functional" $G$ plays crucial role in all the parts of the mathematical analysis: existence and differentiability properties of minimizers and estimates of deviations from the minimizers.
To understand the basic principles of the functional approach to the derivation of a posteriori bounds of the approximation errors we need to make a concise overview of some parts of the duality theory in the calculus of variations.
A consequent exposition functional type a posteriori error estimates for nonlinear variational problems can be found in the papers

and in the book

To understand the structure of functional a posteriori estimates for the considered class of problems we need first discuss three additional topics:

- **Dual and bidual functionals**;
- **Compound functionals**;
- **Uniformly convex functionals**.
Dual (polar) functionals

Hereafter $V^*$ contains all linear continuous functionals defined on $V$. The elements of $V^*$ are marked by stars, $\langle v^*, v \rangle$ is called the duality pairing of the spaces $V$ and $V^*$. Let $J : V \to \mathbb{R}$, then $J^*$ defined by the relation

$$J^*(v^*) = \sup_{v \in V} \{ \langle v^*, v \rangle - J(v) \}$$

is called dual to $J$. If $J$ is a smooth function that increases at infinity faster than any linear function, then $J^*$ is the Legendre transform of $J$. The above general definition comes from Young and Fenchel. The functional $J^*$ is also called polar to $J$. 
The functional

\[ J^{**}(v) = \sup_{v^* \in V^*} \{ \langle v^*, v \rangle - J^*(v^*) \} \]

is called the bidual to \( J \) (or bipolar).
Straightforwardly from the definition, it follows that \( J^* \) and \( J^{**} \) are convex functionals (they are defined as upper bounds of affine functionals).
Formally, one can also define

\[ J^{***}(v^*) := \sup_{v \in V} \{ \langle v^*, v \rangle - J^{**}(v) \}. \]

However, this definition brings nothing new. It is proved that

\[ J^{***}(v^*) = J^*(v^*), \quad \forall v^* \in V^*. \]
Mutually dual functionals

Let $J : V \to \overline{\mathbb{R}} := \{\mathbb{R}, -\infty, +\infty\}$ and $G^* : V^* \to \overline{\mathbb{R}}$ be two functionals defined on a Banach space $V$ and its dual space $V^*$, respectively. These two functionals are called **mutually dual** if

$$(G^*)^* = J \quad \text{and} \quad J^* = G^*.$$
Examples

To illustrate the definitions of conjugate functionals, we present below several examples for functionals defined on the Euclidean space $E^d$. In this case, $V$ and $V^*$ are isometrically isomorphic. Their elements are $d$-dimensional vectors denoted by $\xi$ and $\xi^*$, respectively, so that

$$\langle \xi^*, \xi \rangle = \xi^* \cdot \xi = \xi_i^* \xi_i.$$

These examples have a practical meaning because for a wide class of integral type functionals (in the mechanics they are the energy functionals) finding the dual energy functional is reduced to finding dual to its integrand!
In other words, if the "primal energy functional" has the form

$$G(v) := \int_{\Omega} g(\Lambda v) \, dx$$

where $g$ is the "internal energy" or "dissipative potential", then the so-called "complementary energy" is given by the integral functional

$$G^*(y^*) := \int_{\Omega} g^*(y^*) \, dx,$$

where $g^*$ is conjugate to $g$ in the algebraic sense.
Example 1 (Diffusion problems)

Let \( A = \{a_{ij}\} \) be a real, positive definite matrix and

\[
g(\xi) = \frac{1}{2} A \xi \cdot \xi = \frac{1}{2} a_{ij} \xi_i \xi_j.
\]

Then

\[
g^*(\xi^*) = \sup_{\xi \in \mathbb{E}^d} \left\{ \xi^* \cdot \xi - \frac{1}{2} A \xi \cdot \xi \right\}.
\]

This supremum is attained on an element \( \xi_0 \) such that

\[
\xi^* = A \xi_0 \implies \xi_0 = A^{-1} \xi^*.
\]

Therefore, we have a pair of mutually conjugate functionals

\[
g(\xi) = \frac{1}{2} A \xi \cdot \xi \quad \text{and} \quad g^*(\xi^*) = \frac{1}{2} A^{-1} \xi^* \cdot \xi^*.
\]
In diffusion type boundary–value problems we arrive at the functional (with $y = \nabla \mathbf{v}$)

$$\frac{1}{2} \int_{\Omega} A\mathbf{y} \cdot \mathbf{y} \, dx \quad \mathbf{y} \in L^2(\Omega, \mathbb{R}^n),$$

which is mutually dual to

$$\frac{1}{2} \int_{\Omega} A^{-1}\mathbf{y}^* \cdot \mathbf{y}^* \, dx \quad \mathbf{y}^* \in L^2(\Omega, \mathbb{R}^n)$$
Example 2 (Linear elasticity)

Let $\mathbf{L} = \{L_{ijkl}\}$ be a real, positive definite tensor of the 4-th order and $\mathbf{\tau}$ be a tensor of the second order ($d \times d$–matrix). Then,

$$g(\varepsilon) = \frac{1}{2}\mathbf{L}\varepsilon : \varepsilon = \frac{1}{2}L_{ijkl}\varepsilon_{ij}\varepsilon_{km}.$$ 

Then

$$g^*(\varepsilon^*) = \sup_{\varepsilon \in M_d \times d} \left\{ \varepsilon^* : \varepsilon - \frac{1}{2}\mathbf{A}\varepsilon : \varepsilon \right\}.$$ 

This supremum is attained on an element $\varepsilon_0$ such that

$$\mathbf{\tau}^* = \mathbf{L}\varepsilon_0 \implies \varepsilon_0 = \mathbf{L}^{-1}\varepsilon^*.$$ 

Therefore, we have a pair of mutually dual functionals

$$g(\varepsilon) = \frac{1}{2}\mathbf{L}\varepsilon : \varepsilon \quad \text{and} \quad g^*(\varepsilon^*) = \frac{1}{2}\mathbf{L}^{-1}\varepsilon^* : \varepsilon^*.$$
In linear elasticity problems we arrive at the energy functional in terms of strains \( \varepsilon(v) = \frac{1}{2} (\nabla v + (\nabla v)^T) \)

\[
\frac{1}{2} \int_{\Omega} L \varepsilon : \varepsilon \, dx \quad \varepsilon \in L^2(\Omega, \mathbb{M}^{n \times n}),
\]

which is mutually dual to the ”complementary energy” functional written in terms of stresses \( \varepsilon^*(x) \rightarrow \tau(x) \)

\[
\frac{1}{2} \int_{\Omega} L^{-1} \tau : \tau \, dx \quad \tau \in L^2(\Omega, \mathbb{M}^{n \times n})
\]
Example 3 (Nonlinear elasticity, p-Laplacian)

Consider the functional

$$g(\xi) = \frac{1}{p} |\xi|^p,$$

where $p > 1$ and $|\xi| = (\xi \cdot \xi)^{1/2}$. It is easy to verify that the quantity

$$\xi^* \cdot \xi - \frac{1}{p} |\xi|^p$$

attains a supremum if $\xi = \xi_0$, where $\xi_0$ satisfies the relation

$$\xi^* - |\xi_0|^{p-2} \xi_0 = 0,$$

which yields $|\xi^*| = |\xi_0|^{p-1}$ and $\xi^* \cdot \xi_0 = |\xi_0|^p$. Therefore,

$$g^*(\xi^*) = \xi^* \cdot \xi_0 - \frac{1}{p} |\xi_0|^p = \left(1 - \frac{1}{p}\right) |\xi_0|^p = \frac{1}{p^*} |\xi^*|^{p^*},$$

where $p^* = \frac{p}{p-1}$. 
Thus, we obtain another pair of mutually conjugate functionals

\[ g(\xi) = \frac{1}{p} |\xi|^p \quad \text{and} \quad g^*(\xi^*) = \frac{1}{p^*} |\xi^*|^{p^*}, \]

where \( \frac{1}{p} + \frac{1}{p^*} = 1 \).

Remark

This relation admits generalizations. Namely, let \( \varphi : \mathbb{R} \to \mathbb{R} \) be a proper convex function that is, in addition, odd and let \( \varphi^* : \mathbb{R} \to \mathbb{R} \) be its conjugate. Then

\[ (\varphi(\|u\|_V))^* = \varphi^*(\|u^*\|_{V^*}). \]
In certain nonlinear boundary–value problems we arrive at the functional
(with $y = \nabla v$ or $y = \varepsilon(v)$)

$$\frac{1}{p} \int_{\Omega} |y|^p \, dx \quad y \in L^p(\Omega, \mathbb{R}^n[\mathbb{M}^{n\times n}]),$$

which is mutually dual to

$$\frac{1}{p^*} \int_{\Omega} |y^*|^{p^*} \, dx \quad y^* \in L^{p^*}(\Omega, \mathbb{R}^n[\mathbb{M}^{n\times n}]).$$
Example 4 (Action of external forces)

Let \( g(\xi) \) be a linear functional, i.e.,

\[
g(\xi) = \ell \cdot \xi, \quad \ell \in \mathbb{E}^d.
\]

It is easy to see that

\[
g^*(\xi^*) = \sup_{\xi \in \mathbb{E}^d} \{ \xi^* \cdot \xi - \ell \cdot \xi \} = \begin{cases} 0 & \xi^* = \ell, \\ +\infty & \xi^* \neq \ell. \end{cases}
\]

Denote by \( \mathcal{X}_{\{\ell\}} \) the characteristic functional of the set \( \{\ell\} \subset \mathbb{E}^d \). Then, another pair of mutually conjugate functionals is as follows:

\[
g(\xi) = \ell \cdot \xi \quad \text{and} \quad g^*(\xi^*) = \mathcal{X}_{\{\ell\}}(\xi^*).\]
Thus, for the functional $G: L^2 \rightarrow \mathbb{R}$

$$G(v) := \int_{\Omega} f v \, dx, \quad f \in L^2(\Omega)$$

the respective dual functional is $G^* : L^2 \rightarrow \mathbb{R}$

$$G^*(v^*) = 0 \text{ if } v^* = f, \quad G^*(v^*) = +\infty \text{ in other cases.}$$
Example 5 (Variational inequalities)

Let $g(\xi) = |\xi|$. Then

$$\sup_{\xi}\{\xi^* \cdot \xi - |\xi|\}$$

may be finite or infinite depending on the value of $|\xi^*|$. If $|\xi^*| > 1$, then, obviously, it is infinite. If $|\xi^*| \leq 1$, then, on the one hand,

$$\sup_{\xi}\{\xi^* \cdot \xi - |\xi|\} \leq \sup_{\xi}\{1|\xi| - |\xi|\} = 0.$$

On the other hand, $\sup_{\xi}\{\xi^* \cdot \xi - |\xi|\} \geq \xi^* \cdot \mathbf{0} - \mathbf{0} = 0$. This means that $g^*(\xi^*) = \mathbf{0}$ if $|\xi^*| \leq 1$ and, thus,

$$g(\xi) = |\xi|, \quad g^*(\xi^*) = \chi_{B^*(0,1)}(\xi^*),$$

where $B^*(0,1) = \{\xi^* \in \mathbb{R}^d \mid |\xi^*| \leq 1\}$. 
Thus, for the functional $G : \mathbb{L}^{1} \rightarrow \mathbb{R}$

$$G(v) := \int_{\Omega} |v| \, dx,$$

the respective dual functional is $G^* : \mathbb{L}^{\infty} \rightarrow \mathbb{R}$

$$G^*(v^*) = 0 \text{ if } |v^*(x)| \leq 1 \text{ a.e. in } \Omega, \quad G^*(v^*) = +\infty \text{ in other cases.}$$
Properties of dual functionals

Property 1

If $J : V \to \overline{\mathbb{R}}$ and $G : V \to \overline{\mathbb{R}}$ are such that

$$J(v) \geq G(v), \quad \forall v \in V,$$

then

$$J^*(v^*) \leq G^*(v^*), \quad \forall v^* \in V^*.$$

Proof. We have

$$J^*(v^*) = \sup_{v \in V} \{ \langle v^*, v \rangle - J(v) \} \leq \sup_{v \in V} \{ \langle v^*, v \rangle - G(v) \} = G^*(v^*).$$
Property 2

For any $\lambda > 0$,

$$(\lambda J)^*(v^*) = \lambda J^* \left( \frac{v^*}{\lambda} \right).$$

**Proof.** This property is justified by direct calculations:

$$(\lambda J)^*(v^*) = \sup_{v \in V} \{ \langle v^*, v \rangle - \lambda J(v) \} =$$

$$= \lambda \sup_{v \in V} \left\{ \langle \frac{v^*}{\lambda}, v \rangle - J(v) \right\} = \lambda J^* \left( \frac{v^*}{\lambda} \right).$$
Property 3

Let $J : V \to \bar{\mathbb{R}}$ and $J_\alpha(v) = J(v) + \alpha$, where $\alpha \in \mathbb{R}$. Then

$$J_\alpha^*(v^*) = J^*(v^*) - \alpha.$$

Proof. It follows from the obvious relation

$$\sup_{v \in V} \left\{ \langle v^*, v \rangle - J(v) - \alpha \right\} = \sup_{v \in V} \left\{ \langle v^*, v \rangle - J(v) \right\} - \alpha.$$
Property 4

Let \( \mathbf{v}_0 \in \mathbf{V} \) and \( \mathbf{G}(\mathbf{v}) = \mathbf{J}(\mathbf{v} - \mathbf{v}_0) \). Then

\[
\mathbf{G}^*(\mathbf{v}^*) = \mathbf{J}^*(\mathbf{v}^*) + \langle \mathbf{v}^*, \mathbf{v}_0 \rangle.
\]

Proof. Since

\[
\sup_{\mathbf{v} \in \mathbf{V}} \{ \langle \mathbf{v}^*, \mathbf{v} \rangle - \mathbf{J}(\mathbf{v} - \mathbf{v}_0) \} = \sup_{\mathbf{w} \in \mathbf{V}} \{ \langle \mathbf{v}^*, \mathbf{w} + \mathbf{v}_0 \rangle - \mathbf{J}(\mathbf{w}) \}
\]

\[
= \sup_{\mathbf{w} \in \mathbf{V}} \{ \langle \mathbf{v}^*, \mathbf{w} \rangle - \mathbf{J}(\mathbf{w}) \} + \langle \mathbf{v}^*, \mathbf{v}_0 \rangle = \mathbf{J}^*(\mathbf{v}^*) + \langle \mathbf{v}^*, \mathbf{v}_0 \rangle,
\]

we arrive at the required relation.
Property 5

If \( G(v) = \min_{i=1,...,N} \{ J_i(v) \} \), then \( G^*(v^*) = \max_{i=1,...,N} \{ J_i^*(v^*) \} \).

**Proof.** We have

\[
G^*(v^*) = \sup_{v \in V} \{ \langle v^*, v \rangle - \min_{i=1,...,N} \{ J_i(v) \} \}
\]

\[
= \sup_{v \in V} \{ \langle v^*, v \rangle + \max_{i=1,...,N} \{ -J_i(v) \} \}
\]

\[
= \sup_{v \in V} \max_{i=1,...,N} \{ \langle v^*, v \rangle - J_i(v) \}
\]

\[
= \max_{i=1,...,N} \sup_{v \in V} \{ \langle v^*, v \rangle - J_i(v) \} = \max_{i=1,...,N} \{ J_i^*(v^*) \}.
\]
Property 6

If $G(v) = \max_{i=1,\ldots,N} \{ J_i(v) \}$, then $G^*(v^*) \leq \min_{i=1,\ldots,N} \{ J^*_i(v^*) \}$.

Proof. By definition, we have

$$G^*(v^*) = \sup_{v \in V} \{ \langle v^*, v \rangle - \max_{i=1,\ldots,N} \{ J_i(v) \} \}$$

$$= \sup_{v \in V} \{ \langle v^*, v \rangle + \min_{i=1,\ldots,N} \{ -J_i(v) \} \}$$

$$= \sup_{v \in V} \min_{i=1,\ldots,N} \{ \langle v^*, v \rangle - J_i(v) \}.$$ 

Now we apply $\sup \inf \leq \inf \sup$ relation to $\langle v^*, v \rangle - J_i(v)$. Then,

$$G^*(v^*) \leq \min_{i=1,\ldots,N} \sup_{v \in V} \{ \langle v^*, v \rangle - J_i(v) \} = \min_{i=1,\ldots,N} \{ J^*_i(v^*) \}.$$
Subdifferential

**Definition**

The functional $J: V \rightarrow \mathbb{R}$ is called subdifferentiable at $v_0$ if there exists an affine minorant $\ell \in AM(J)$ such that $J(v_0) = \ell(v_0)$. A minorant with this property is called the **exact minorant** at $v_0$.

Obviously, any affine minorant exact for $J$ at $v_0$ has the form

$$\ell(v) = \langle v^*, v - v_0 \rangle + J(v_0), \quad \ell(v) \leq J(v), \quad \forall v \in V.$$  

The element $v^*$ is called a **subgradient** of $J$ at $v_0$. 
The set of all subgradients of $J$ at $v_0$ forms a **subdifferential**, which is usually denoted by $\partial J(v_0)$. It may be empty or contain one element or infinitely many elements.

An important property of convex functionals follows directly from the above definition. For a convex functional $J$ at a point $v_0$ where it is finite, the exact affine minorant is evidently **exist!**

In other words, there is at least one element $v^* \in \partial J(v_0)$ that ”creates” an affine minorant such that

$$\langle v^*, v \rangle - \alpha \leq J(v), \quad \forall v \in V,$$

$$\langle v^*, v_0 \rangle - \alpha = J(v_0).$$

By subtracting, we obtain

$$J(v) - J(v_0) \geq \langle v^*, v - v_0 \rangle.$$

The inequality (313) presents the **basic incremental relation for convex functionals**.
Compound functionals

Let $J$ and $J^*$ be a pair of mutually dual convex functionals.

The functional $D_J : V \times V^* \to \mathbb{R}$ of the form

$$D_J(v, v^*) := J(v) + J^*(v^*) - \langle v^*, v \rangle.$$

is called it the compound functional associated with these pair of functionals.

We will see that compound functionals play an important role in the a posteriori analysis of linear and nonlinear variational problems.
Compound functionals are always nonnegative. Indeed,

\[ J^*(v^*) = \sup_{v \in V} (\langle v^*, v \rangle - J(v)) \geq \langle v^*, v \rangle - J(v) \quad \forall v \in V \]

and

\[ J^*(v^*) + J(v) - \langle v^*, v \rangle \geq 0 \quad \forall v, v^* \]
Compound functionals may vanish only on special sets, where $v$ and $v^*$ satisfy certain relations.

**Theorem**

Let $J$ be a proper convex functional and $J^*$ be its polar. Then, the following two statements are equivalent:

\[
J(v) + J^*(v^*) - \langle v^*, v \rangle = 0, \tag{313}
\]

\[
v^* \in \partial J(v) \quad \text{and} \quad v \in \partial J^*(v^*). \tag{314}
\]

Relations (314) are also called **duality relations** for the pair $(v, v^*)$. 
Proof.

Assume that $v^* \in \partial J(v)$, i.e,

$$ J(w) \geq J(v) + \langle v^*, w - v \rangle, \quad \forall w \in V. $$

Hence,

$$ \langle v^*, v \rangle - J(v) \geq \langle v^*, w \rangle - J(w), \quad \forall w \in V $$

and, consequently,

$$ \langle v^*, v \rangle - J(v) \geq \sup_{w \in V} \{ \langle v^*, w \rangle - J(w) \} = J^*(v^*), $$

what leads to the conclusion that $J^*(v^*) + J(w) - \langle v^*, w \rangle \leq 0$. But the left–hand side is nonnegative, so that we obtain $D_J(v^*, v) = 0$. 
Assume that \( \mathbf{v} \in \partial J^*(\mathbf{v}^*) \). Then
\[
J^*(\mathbf{w}^*) \geq J^*(\mathbf{v}^*) + \langle \mathbf{w}^* - \mathbf{v}^*, \mathbf{v} \rangle,
\]
and we continue similarly to the previous case:
\[
\langle \mathbf{v}^*, \mathbf{v} \rangle - J^*(\mathbf{v}^*) \geq \langle \mathbf{w}^*, \mathbf{v} \rangle - J^*(\mathbf{w}^*), \quad \forall \mathbf{w}^* \in \mathbf{V}^*,
\]
\[
\langle \mathbf{v}^*, \mathbf{v} \rangle - J^*(\mathbf{v}^*) \geq J^{**}(\mathbf{v}) = J(\mathbf{v}).
\]
Thus, we again arrive at the conclusion that it can only be if \( D_J(\mathbf{v}^*, \mathbf{v}) = 0 \).
Assume that $D_J(v^*, v) = 0$. Since

$$J^*(v^*) = \sup_{w \in V} \{ \langle v^*, w \rangle - J(w) \},$$

we obtain

$$0 = J(v) + J^*(v^*) - \langle v^*, v \rangle \geq J(v) - J(w) - \langle v^*, v - w \rangle, \quad \forall w \in V.$$ 

Rewrite this inequality in a more familiar form:

$$J(w) - J(v) \geq \langle v^*, w - v \rangle, \quad \forall w \in V,$$

which means that $J(v) + \langle v^*, v - w \rangle$ is an exact affine minorant of $J$ (at $v$) and, consequently, $v^* \in \partial J(v)$. The proof of the fact that $v^* \in \partial J^*(v^*)$ is quite analogous.
Properties of compound functionals

First, we note that, $D_G(y, y^*)$ is convex with respect to $y$ and $y^*$, but, in general, $D_G(y, y^*)$ is a nonconvex functional on $Y \times Y^*$. This fact is easily observed in the simplest case $Y = \mathbb{R}$ if set

$$G(y) = \frac{1}{\alpha} |y|^\alpha \quad G^*(y) = \frac{1}{\alpha^*} |y|^{\alpha^*}.$$  

Only for $\alpha = 2$ we have a convex functional

$$D_G(y, y^*) = \frac{1}{2} |y|^2 + \frac{1}{2} |y^*|^2 - yy^* = \frac{1}{2} (y - y^*)^2.$$  

For other $\alpha \in (1, +\infty)$ $D_G$ is nonconvex on $\mathbb{R} \times \mathbb{R}$. 

Example 1: \( D(\xi_1, \xi_2) = \frac{1}{3}|\xi_1|^3 + \frac{2}{3}|\xi_2|^{3/2} - \xi_1 \xi_2 \)
Example 2: \( D(\xi_1, \xi_2) = \frac{5}{6} |\xi_1|^{6/5} + \frac{1}{6} |\xi_2|^6 - \xi_1 \xi_2 \)

Compound functional on \( \mathbb{R} \times \mathbb{R} \) and its level lines
However, they have an important property, which is to some extent similar to convexity.

**Theorem**

For any $y_1, y_2 \in Y$ and $y_1^*, y_2^* \in Y^*$,

$$D_G\left(\frac{y_1+y_2}{2}, \frac{y_1^*+y_2^*}{2}\right) \leq \frac{1}{4}\left(D_G(y_1, y_1^*) + D_G(y_1, y_2^*) + D_G(y_2, y_1^*) + D_G(y_2, y_2^*)\right)$$
Proof

From the definition it follows that

\[ \mathbf{D}_G \left( y, \frac{y_1^* + y_2^*}{2} \right) = \mathbf{G}(y) + \mathbf{G}^* \left( \frac{y_1^* + y_2^*}{2} \right) - \left\langle \frac{y_1^* + y_2^*}{2}, y \right\rangle \]
\[ \leq \frac{1}{2} \left( \mathbf{D}_G(y, y_1^*) + \mathbf{D}_G(y, y_2^*) \right) \]

and

\[ \mathbf{D}_G \left( \frac{y_1 + y_2}{2}, y^* \right) = \mathbf{G} \left( \frac{y_1 + y_2}{2} \right) + \mathbf{G}^* \left( y^* \right) - \left\langle y^*, \frac{y_1 + y_2}{2} \right\rangle \]
\[ \leq \frac{1}{2} \left( \mathbf{D}_G(y_1, y^*) + \mathbf{D}_G(y_2, y^*) \right). \]

Therefore,

\[ \mathbf{D}_G \left( \frac{y_1 + y_2}{2}, \frac{y_1^* + y_2^*}{2} \right) \leq \frac{1}{2} \left( \mathbf{D}_G(y_1, \frac{y_1^* + y_2^*}{2}) + \mathbf{D}_G(y_2, \frac{y_1^* + y_2^*}{2}) \right) \]

and we arrive at the required estimate.
If $G$ and $G^*$ are Gateaux differentiable, then

$$\langle y^* - G'(y), G^*(y^*) - y \rangle \geq D_G(y, y^*).$$

Note, that from this relation we conclude that $D_J$ vanishes if the duality relations are satisfied.
Uniformly convex functionals

Let a proper l.s.c. functional $\Upsilon : Y \to \overline{\mathbb{R}}$ be subject to the conditions

$$\Upsilon(y) \geq 0, \quad \forall y \in Y, \quad \Upsilon(y) = 0 \iff y = 0_Y.$$

**Definition**

A convex functional $J : Y \to \overline{\mathbb{R}}$ is called uniformly convex in $B(0_Y, \delta)$ if there exists a functional $\Upsilon_\delta$ such that $\Upsilon_\delta \not\equiv 0$ and for all $y_1, y_2 \in B(0_Y, \delta)$ the following inequality holds:

$$J \left( \frac{y_1 + y_2}{2} \right) + \Upsilon_\delta(y_1 - y_2) \leq \frac{1}{2} \left( J(y_1) + J(y_2) \right).$$  \hspace{1cm} (315)

The functional $\Upsilon_\delta$ enforces standard convexity inequality. For this reason, it is called a **forcing** functional.
It is clear that any uniformly convex functional is convex in $\mathcal{B}(0_Y, \delta)$. Now we establish two important inequalities that hold for uniformly convex functionals.

**Theorem**

If $J : Y \to \overline{\mathbb{R}}$ is uniformly convex in $\mathcal{B}(0_Y, \delta)$ and Gâteaux differentiable in $\mathcal{B}(0_Y, \delta)$, then for any $y, z \in \mathcal{B}(0_Y, \delta)$ the following relations hold:

\[
J(z) \geq J(y) + \langle J'(y), z - y \rangle + 2\Upsilon_\delta(z - y)
\]

and

\[
\langle J'(z) - J'(y), z - y \rangle \geq 2\Upsilon_\delta(z - y) + 2\Upsilon_\delta(y - z).
\]
Proof.

We have \( \Upsilon_\delta(z - y) \leq \frac{1}{2} J(z) + \frac{1}{2} J(y) - J(\frac{z+y}{2}) \).

Since \( J \) is convex and differentiable

\[
J \left( \frac{z + y}{2} \right) = J \left( y + \frac{z - y}{2} \right) \geq J(y) + \left\langle J'(y), \frac{z - y}{2} \right\rangle,
\]

and, therefore,

\[
2\Upsilon_\delta(z - y) \leq J(z) - J(y) - \left\langle J'(y), z - y \right\rangle.
\]

We can rewrite it replacing \( z \) by \( y \)

\[
2\Upsilon_\delta(y - z) \leq J(y) - J(z) + \left\langle J'(z), z - y \right\rangle
\]

and obtain the second inequality.
Deviations from the minimizer

**Theorem**

Let a functional $J$ be uniformly convex in $B(0_Y, \delta)$ and $y_m \in B(0_Y, \delta)$ be the minimizer of $J$.

$$\mathcal{V}_\delta(z - y_m) \leq \frac{1}{2} (J(z) - J(y_m)), \quad \forall z \in B(0_Y, \delta).$$  \hfill (316)

**Proof.**

Since $J \left( \frac{y_m + z}{2} \right) \geq J(y_m)$, we obtain

$$\mathcal{V}_\delta(z - y_m) \leq \frac{1}{2} J(y_m) + \frac{1}{2} J(z) - J \left( \frac{y_m + z}{2} \right) \leq$$

$$\leq \frac{1}{2} (J(z) - J(y_m)).$$
Estimate (316) is the first step in deriving a posteriori error estimates of the functional type by means of the variational techniques. It shows that deviations from the minimizer (measured in terms of the functional $\mathcal{V}_\delta$) are controlled by the difference of the functionals.
Corollary 1

Rewrite (315) in the form

$$\Upsilon_\delta (z - y_m) + J \left( \frac{y_m + z}{2} \right) - J(y_m) \leq \frac{1}{2} \left( J(z) - J(y_m) \right).$$

By virtue of (316), we have

$$J \left( \frac{y_m + z}{2} \right) - J(y_m) \geq 2 \Upsilon_\delta \left( \frac{z - y_m}{2} \right)$$

and, therefore, we arrive at the strengthened estimate

$$\Upsilon_\delta (z - y_m) + 2 \Upsilon_\delta \left( \frac{z - y_m}{2} \right) \leq \frac{1}{2} \left( J(z) - J(y_m) \right). \quad (317)$$
Corollary 2

Assume that $J$ is twice differentiable in the vicinity of $y_m$ and satisfies the finite increment relation

$$J \left( \frac{y_m + z}{2} \right) = J(y_m) + \left< J'(y_m), \frac{z - y_m}{2} \right> +$$
$$+ \frac{1}{2} \left< J'' \left( y_m + \xi \frac{z + y_m}{2} \right) \frac{z - y_m}{2}, \frac{z - y_m}{2} \right>,$$

where $\xi \in (0, 1)$. Since $J'(y_m) = 0_{Y^*}$, we have another estimate:

$$\mathcal{R}_\delta(z - y_m) + \frac{1}{8} \left< J'' \left[ (1 + \frac{\xi}{2})y_m + \frac{\xi}{2} z \right] (z - y_m), z - y_m \right> \leq$$
$$\leq \frac{1}{2} \left( J(z) - J(y_m) \right). \quad (318)$$
Example 1

Consider a self-adjoint operator $A \in \mathcal{L}(H, H)$ defined on a Hilbert space $H$ with scalar product $(.,.)$. Assume that it satisfies the condition

$$\alpha_1 \|y\|^2 \leq G(y) := (Ay, y) \leq \alpha_2 \|y\|^2, \quad \forall y \in H.$$ 

For $J(y) = G(y) + (\ell, y)$, $\ell \in H$ we have

$$\frac{1}{2} G(y) + \frac{1}{2} G(z) - G\left(\frac{y+z}{2}\right) =$$

$$= \frac{1}{4} (Ay, y) + \frac{1}{4} (Az, z) - \frac{1}{8} (A(y+z), y+z) =$$

$$= \frac{1}{8} (A(z-y), (z-y)),$$

the functional $G$ is uniformly convex in any ball with

$$\Upsilon(z-y) = \frac{1}{8} (A(z-y), (z-y)).$$
Thus, from (316) we have

\[
\frac{1}{8} \langle A(z - y_m), (z - y_m) \rangle \leq \frac{1}{2} \langle J(z) - J(y_m) \rangle, \quad \forall z
\]

However (318) gives a better estimate

\[
\frac{1}{2} \langle A(z - y_m), (z - y_m) \rangle \leq J(z) - J(y_m).
\]  

(319)

Note that for quadratic type functionals this estimate holds as equality. Indeed,

\[
J(z) - J(y_m) = \langle Ay_m + \ell, z - y_m \rangle + \frac{1}{2} \langle A(z - y_m), z - y_m \rangle.
\]

and the minimizer \( y_m \) satisfies the relation

\[
(AY_m + \ell, y) = 0, \quad \forall y \in Y.
\]

Therefore, (319) holds as equality.
Theorem

Let $J_1$ and $J_2$ be uniformly convex in $B(0_Y, \delta)$ with functionals $\Upsilon_{1\delta}$ and $\Upsilon_{2\delta}$, respectively. Then the functional

$$\mu_1 J_1 + \mu_2 J_2,$$

where $\mu_1, \mu_2 \geq 0$, is uniformly convex in $B(0_Y, \delta)$ with

$$\Upsilon_{\delta} = \mu_1 \Upsilon_{1\delta} + \mu_2 \Upsilon_{2\delta}.$$

Proof.

The proposition follows directly from definition of uniform convexity.
Example 2

Consider the functional

$$J(y) = \frac{1}{2} \langle Ay, y \rangle + (\ell, y) + \Psi(y),$$

where $\Psi(y)$ is a convex and l.s.c. functional. Applying the above Theorem with $\mu_1 = \mu_2 = 1$,

$$J_1(y) = \frac{1}{2} \langle Ay, y \rangle + (\ell, y) \quad J_2(y) = \Psi(y),$$

we see that $J$ is uniformly convex with functional $\Upsilon$ defined in Example 1.
Theorem

Let $J_1$ and $J_2$ be uniformly convex in $B(0_Y, \delta)$ with functionals $\Upsilon_{1\delta}$ and $\Upsilon_{2\delta}$, respectively. Then the functional

$$J(y) = \max\{J_1(y), J_2(y)\}$$

is uniformly convex in $B(0_Y, \delta)$ with

$$\Upsilon_{\delta} = \min\{\Upsilon_{1\delta}, \Upsilon_{2\delta}\}.$$
Proof. We have

\[
\frac{1}{2} J(y) + \frac{1}{2} J(z) - J\left(\frac{y+z}{2}\right) = \frac{1}{2} \max\{J_1(y), J_2(y)\} + \\
+ \frac{1}{2} \max\{J_1(z), J_2(z)\} - \max \left\{ J_1\left(\frac{y+z}{2}\right), J_2\left(\frac{y+z}{2}\right) \right\}.
\]

Assume that

\[
\max \left\{ J_1\left(\frac{y+z}{2}\right), J_2\left(\frac{y+z}{2}\right) \right\} = J_1\left(\frac{y+z}{2}\right).
\]

Then

\[
\frac{1}{2} (J(y) + J(z)) - J\left(\frac{y+z}{2}\right) \geq \\
\geq \frac{1}{2} (J_1(y) + J_1(z)) - J_1\left(\frac{y+z}{2}\right) \geq \gamma_1 \delta (z - y).
\]
If we have an opposite situation, i.e.,

$$\max \left\{ J_1 \left( \frac{y+z}{2} \right), J_2 \left( \frac{y+z}{2} \right) \right\} = J_2 \left( \frac{y+z}{2} \right),$$

then

$$\frac{1}{2} J(y) + \frac{1}{2} J(z) - J \left( \frac{y+z}{2} \right) \geq \Upsilon_2 \delta (z - y).$$

Thus, in both cases the lower bound is given by the functional

$$\min \left\{ \Upsilon_1 \delta (z - y), \Upsilon_2 \delta (z - y) \right\}.$$
Example 3. Power growth functionals

Let

\[ G(y) = \frac{1}{\alpha} \int_{\Omega} |y|^\alpha \, dx \quad F(v) = \int_{\Omega} fv \, dx, \]

where \( \alpha > 1 \). Then Problem \( P \) is to minimize the functional

\[ J_\alpha(v) := \int_{\Omega} \left( \frac{1}{\alpha} |\nabla v|^\alpha + fv \right) \, dx \]

over the space \( V = \{v \in H^\alpha(\Omega) \mid v = 0 \text{ on } \partial\Omega\} \).
Problem $\mathcal{P}^*$ is to maximize the functional

$$l_{\alpha^*}(y^*) = -\frac{1}{\alpha^*} \int_{\Omega} |y^*|^{\alpha^*} \, dx$$

over the set

$$Q_f^* = \left\{ y^* \in Y^* : = L^\alpha(\Omega, \mathbb{R}^n) \mid \int_{\Omega} y^* \cdot \nabla w dx = \int_{\Omega} f w dx \quad \forall w \in V \right\}.$$
For $\alpha \geq 2$ uniform convexity of $G(y)$ follows from the first Clarkson’s inequality

$$\int_{\Omega} \left| \frac{y_1 + y_2}{2} \right|^\alpha \, dx + \int_{\Omega} \left| \frac{y_1 - y_2}{2} \right|^\alpha \, dx \leq \frac{1}{2} \int_{\Omega} \left( |y_1|^\alpha + |y_2|^\alpha \right) \, dx,$$

which is valid for all $y_1, y_2 \in Y$.

See S. L. Sobolev. *Some Applications of Functional Analysis in Mathematical Physics*. Hence, we observe that in this case

$$\mathcal{T}_\Theta(z) = \frac{1}{\alpha} \| z \|_{\alpha, \Omega}^\alpha.$$

and

$$\frac{1}{2} \int_{\Omega} |\nabla (v - u)|^\alpha \, dx \leq \frac{1}{2} \left( J_{\alpha}(v) - I_{\alpha}(q^*) \right), \forall q^* \in Q^*_f.$$
For $1 < \alpha \leq 2$, the functional $G$ is also uniformly convex. This fact follows from the second Clarkson’s inequality

\[
\left( \int_{\Omega} \left( \frac{y_1 + y_2}{2} \right)^\alpha \, dx \right)^{\frac{1}{\alpha-1}} + \left( \int_{\Omega} \left( \frac{y_1 - y_2}{2} \right)^\alpha \, dx \right)^{\frac{1}{\alpha-1}} \leq \left( \frac{1}{2} \int_{\Omega} (|y_1|^{\alpha} + |y_2|^{\alpha}) \, dx \right)^{\frac{1}{\alpha-1}}.
\]

However, in this case, the functional $\Upsilon_\delta$ depends on the radius $\delta$ of a ball $B(0_Y, \delta)$ that contains $y_1$ and $y_2$, so that the estimate holds with

\[
\Upsilon_\delta(z) = \delta^{\frac{\alpha-2}{\alpha-1}} \kappa \|z\|^{\frac{\alpha}{\alpha-1}}_{\alpha, \Omega},
\]

where $\kappa = \frac{1}{\kappa_0 + 1}$ and $\kappa_0$ is the integer part of $\frac{1}{\alpha-1}$. 
Now we introduce a general scheme for deriving a posteriori error estimates by using duality theory of the calculus of variations. We consider variational problems of the form

$$\inf_{v \in V} \{ F(v) + G(\Lambda v) \},$$

where $F : V \to \mathbb{R}$ is a convex lower semicontinuous functional, $G : Y \to \mathbb{R}$ is a uniformly convex functional, $V$ and $Y$ are reflexive Banach spaces and $\Lambda : V \to Y$ is a bounded linear operator.
Consider the general variational problem: find $u$ in a Banach space $V$ such that

$$J(u, \Lambda u) = \inf_{v \in V} J(v, \Lambda v),$$

(320)

where $J(v) = F(v) + G(\Lambda v)$, $F$ is a convex, lower semicontinuous functional, $G$ is a uniformly convex functional and $\Lambda : V \rightarrow Y$ is a bounded linear operator. $V$ and $Y$ are reflexive Banach spaces endowed with the norms $\| \cdot \|_V$ and $\| \cdot \|$, respectively.
Dual spaces are denoted by $V^*$ and $Y^*$ with duality pairings $\langle . , . \rangle$ and $\langle \langle . , . \rangle \rangle$, respectively. The spaces $Y$ and $Y^*$ are endowed with the norms $\| . \|$ and $\| . \|_*$. We assume that
\[
\| \Lambda w \| \geq c_0 \| w \|_V \quad \forall w \in V,
\] (321)
where $c_0$ is a positive constant independent of $w$.
In addition to $\Lambda$, we introduce its conjugate $\Lambda^* : Y^* \to V^*$. This amounts to say that
\[
\langle \langle y^*, \Lambda v \rangle \rangle = \langle \Lambda^* y^*, v \rangle \quad \forall y^* \in Y^*, \, v \in V.
\] (322)

$J(v, \Lambda v) := F(v) + G(\Lambda v)$ is assumed to be coercive on $V$, i.e.
\[
J(v, \Lambda v) \to +\infty \text{ if } \| v \|_V \to +\infty.
\]
Primal and Dual Problems

**Problem $\mathcal{P}$.** Find $u \in V$ such that

$$J(u, \Lambda u) = \inf \mathcal{P} := \inf_{v \in V} J(v, \Lambda v).$$

(323)

The problem dual to (323) is (see e.g. I. Ekeland and R. Temam *Convex analysis and variational problems*. North-Holland, Amsterdam, 1976.)

**Problem $\mathcal{P}^*$.** Find $p^* \in Y^*$ such that

$$-J^*(\Lambda^* p^*, -p^*) = \sup \mathcal{P}^* := \sup_{y^* \in Y^*} -J^*(\Lambda^* y^*, -y^*),$$

(324)

$$J^*(\Lambda^* y^*, -y^*) := F^*(\Lambda^* y^*) + G^*(-y^*),$$

where $F^*$ and $G^*$ are the functionals conjugate of $F$ and $G$, respectively.
Theorem (1)

If the functional $F$ is finite at some $u_0 \in V$ and the functional $G$ is continuous and finite at $\Lambda u_0 \in Y$, then there exists a minimizer $u$ to Problem $P$ and a maximizer $p^*$ to Problem $P^*$. Besides,

$$\inf P = \sup P^*$$  \hspace{1cm} (325)

and the following duality relations hold

(i) $F(u) + F^*(\Lambda^* p^*) - \langle \Lambda^* p^*, u \rangle = 0,$

(ii) $G(\Lambda u) + G^*(-p^*) + \langle p^*, \Lambda u \rangle = 0.$  \hspace{1cm} (326)

Above relations are equivalent to

(i) $\Lambda^* p^* \in \partial F(u), \quad$ (ii) $-p^* \in \partial G(\Lambda u).$
Problems with uniformly convex functionals

We recall (see Lecture 4) that a continuous functional $G : Y \rightarrow \mathbb{R}$ is uniformly convex in a ball $B(0, \delta) := \{y \in Y \mid \|y\| < \delta\}$ if there exists a continuous functional $\Phi_\delta : Y \rightarrow \mathbb{R}_+$ such that $\Phi_\delta(y) = 0$ only if $y = 0$ and

$$G\left(\frac{y_1 + y_2}{2}\right) + \Phi_\delta(y_2 - y_1) \leq \frac{1}{2} (G(y_1) + G(y_2)) \quad \forall y_1, y_2 \in B(0, \delta).$$

Usually, $\Phi_\delta$ is given by a continuous strictly increasing function of the norm $\|y\|$.

General form of a posteriori estimates for uniformly convex variational problems was established in

Theorem (2)

Assume that the above conditions on $F$ and $G$ are satisfied and

(i) $G$ is uniformly convex on a ball $B(0, \delta)$,
(ii) the solution $u$ of Problem $P$ and an element $v \in V$ are such, that

$\Lambda u, \Lambda v \in B(0, \delta)$.

Then, for any $y^* \in Y^*$

$$
\Phi_\delta (\Lambda(v - u)) \leq M_\oplus (v, y^*) := D_F(\Lambda^*y^*, v) + D_G(y^*, \Lambda v)
$$

(327)

where

$$
D_F(\Lambda^*y^*, v) := \frac{1}{2} \left( F(v) + F^*(\Lambda^*y^*) - \langle \Lambda^*y^*, v \rangle \right),
$$

$$
D_G(y^*, \Lambda v) := \frac{1}{2} \left( G(\Lambda v) + G^*(-y^*) + \langle y^*, \Lambda v \rangle \right).
$$
Proof

Since $F$ is convex and $G$ is uniformly convex we obtain

$$
\Phi_\delta (\Lambda (v - u)) + G(\Lambda (\frac{v+u}{2})) + F(\frac{v+u}{2}) \leq \\
\frac{1}{2} \left[ (F(v) + G(\Lambda v)) + (F(u) + G(\Lambda u)) \right].
$$

The element $u$ is a minimizer, therefore

$$
G(\Lambda u) + F(u) = J(u) \leq G(\Lambda (\frac{u+v}{2})) + F(\frac{u+v}{2})
$$

and we have

$$
\Phi_\delta (\Lambda (v - u)) + G(\Lambda u) + F(u) \leq \\
\frac{1}{2} \left[ (F(v) + G(\Lambda v)) + (F(u) + G(\Lambda u)) \right].
$$
From the above we observe that

\[
\Phi_\delta (\Lambda e) \leq \frac{1}{2} \left[ (F(v) + G(\Lambda v)) - (F(u) + G(\Lambda u)) \right] = \\
= \frac{1}{2} (J(v, \Lambda v) - J(u, \Lambda u)) \quad \forall v \in B(0, \delta).
\]

In view of Theorem 1,

\[
J(u, \Lambda u) = \inf \mathcal{P} = \sup \mathcal{P}^* = -F^*(\Lambda^* p^*) - G^*(-p^*).
\]

Since \( p^* \) is a solution of the dual problem, we have

\[
-J^*(\Lambda^* p^*, -p^*) \geq -J^*(\Lambda^* y^*, -y^*) \quad \forall y^* \in Y^*,
\]

so that

\[
J(u, \Lambda u) \geq -F^*(\Lambda^* y^*) - G^*(-y^*).
\]
Therefore

\[ \Phi_\delta (\Lambda e) \leq \frac{1}{2} (F(v) + G(\Lambda v) + F^*(\Lambda^* p^*) + G^*(-p^*)) \leq \frac{1}{2} \left( F(v) + G(\Lambda v) + F^*(\Lambda^* y^*) + G^*(-y^*) \right) . \]

However, by (322) we observe that

\[ \langle \langle y^*, \Lambda v \rangle \rangle - \langle \Lambda^* y^*, v \rangle = 0 \ \forall y^* \in Y^*, \ v \in V . \]

We add this zero term to the above relation and obtain the required estimate.

\[ \square \]
The right–hand side of (327) is the sum of two compound functionals

\[ M_F : V^* \times V \rightarrow \mathbb{R} \quad \text{and} \quad M_G : Y^* \times Y \rightarrow \mathbb{R}. \]

They are nonnegative and vanishes if and only if \( v \) and \( y^* \) satisfy the relations (326)(i)–(ii).

Therefore, \( M_\oplus(v, y^*) \) is, in fact, a measure of the error in the duality relations for the pair \((v, y^*)\).

It vanishes if and only if \( v = u \) and \( y^* = p^* \).
Let the functional $\mathbf{F}$ be uniformly convex on $\mathbf{V}$ with a forcing functional $\varphi_\delta$. Then the ”forcing functional” has the form we have

$$\Phi_\delta (\Lambda e) + \varphi_\delta (e) \leq \frac{1}{2} (J(v, \Lambda v) - J(u, \Lambda u))$$

(328)

and, as a result, (327) is replaced by the strengthened estimate

$$\Phi_\delta (\Lambda e) + \varphi_\delta (e) \leq M_\oplus (v, y^*) \quad \forall y^* \in Y^*$$. 

(329)
It is not difficult to verify that

\[
M_\oplus(v, y^*) - M_\oplus(v, p^*) = \\
= \frac{1}{2} (F(v) + F^*(\Lambda^* y^*) - \langle \Lambda^* y^*, v \rangle + G(\Lambda v) + G^*(-y^*) + \langle y^*, \Lambda v \rangle) - \\
\frac{1}{2} (F(v) + F^*(\Lambda^* p^*) - \langle \Lambda^* p^*, v \rangle + G(\Lambda v) + G^*(-p^*) + \langle p^*, \Lambda v \rangle) = \\
= J^*(\Lambda^* y^*, -y^*) - J^*(\Lambda^* p^*, -p^*) = \geq 0.
\]

Therefore, for any \( v \) the right-hand side of (327) is minimal if \( y^* = p^* \). Consequently, to make the estimate effective we have to find some \( y^* \) close to \( p^* \) in \( Y^* \). A simple way to obtain a function ”close” to \( p^* \) it to use duality relations. To this end, we set \( y^* = \sigma^*(v) \), where

\[-\sigma^*(v) \in \partial G(\Lambda v) \subset Y^*.\]
In this case,

\[ M_G(\sigma^*(v), \Lambda v) = 0 \]

and we get the estimate

\[ \Phi_\delta(\Lambda e) \leq M_F(\Lambda^* \sigma^*(v), v) \]  \hfill (330)

whose right-hand side depends on \( v \) only. However, the estimate (330) cannot be directly applied in one practically important case which we consider below.
Example. Diffusion problem with Robin conditions

Consider the variational problems for the functional

$$J(v, \nabla v) = \int_{\Omega} \left( \frac{1}{2} |\nabla v|^2 + \frac{\delta}{2} |v|^2 \right) dx + \int_{\partial_2 \Omega} \left( \frac{\alpha}{2} |v|^2 - gv \right) ds.$$

Our problem is to minimize $J$ on the set of functions vanishing at $\partial_1 \Omega$. Minimizer $u$ of this variational problem is related to the system

$$-\Delta u + \delta u = 0, \quad \text{in } \Omega,$$

$$\frac{\partial u}{\partial n} + \alpha u - g = 0, \quad \text{on } \partial_2 \Omega.$$

On $\partial_2 \Omega$ the solution satisfies the so-called Robin boundary condition. Let us show that the respective functional a posteriori estimate for the problem with Robin type boundary conditions easily follows from the above general estimate.
We set

\[ \Lambda v := \nabla v, \]

\[ G(\Lambda w) = \int_{\Omega} \frac{1}{2} |\nabla v|^2 \, dx \]

and

\[ F(v) = \int_{\Omega} \frac{\delta}{2} |v|^2 \, dx + \int_{\partial_2 \Omega} \left( \frac{\alpha}{2} |v|^2 - g v \right) \, ds. \]
Since

$$\int_{\Omega} y^* \cdot \nabla v dx = \int_{\Omega} -\text{div} y^* v dx + \int_{\partial_2 \Omega} (y^* n) v ds,$$

we observe that $\Lambda^* y^* = \{-\text{div} y^* |_{\Omega}, y^* \cdot n |_{\partial_2 \Omega}\}$. In the considered case,

$$\langle y^*, y \rangle := \int_{\Omega} y^* \cdot y dx;$$

$$G^*(-y^*) = \sup_y \int_{\Omega} (-y^* \cdot y - \frac{1}{2} |y|^2) dx = \int_{\Omega} \frac{1}{2} |y^*|^2 dx.$$
Therefore,

\[
G(\Lambda v) + G^*(\Lambda y^*) + \langle y^*, \Lambda v \rangle = \int_{\Omega} \left( \frac{1}{2} |\nabla v|^2 + \frac{1}{2} |y^*|^2 + \nabla v \cdot y^* \right) dx.
\]

Next, in general,

\[
\langle \langle \Lambda^* y^*, v \rangle \rangle = -\langle -\text{div} y^*, v \rangle_{H^{-1}(\Omega)} + \langle y^* \cdot n, v \rangle_{H^{-1/2}(\partial_2 \Omega)}.
\]

However, if we assume that \( y^* \) is sufficiently regular, then

\[
\langle \langle \Lambda^* y^*, v \rangle \rangle = \int_{\Omega} -\text{div} y^* v dx + \int_{\partial_2 \Omega} y^* \cdot n dv ds.
\]
Now,

\[ F^*(\Lambda^*y^*) = \sup_v \left\{ \int \Omega -\text{div}^*v \, dx + \int_{\partial_2\Omega} y^* \cdot n v \, ds - F(v) \right\} = \]

\[ \sup_v \left\{ \int \Omega -\text{div}^*v \, dx + \int_{\partial_2\Omega} y^* \cdot n v \, ds - \int \Omega \frac{\delta}{2} |v|^2 \, dx - \int_{\partial_2\Omega} \left( \frac{\alpha}{2} |v|^2 - gv \right) \, ds \leq \right\} \]

\[ \sup_{v \in L_2(\Omega)} \left\{ \int \Omega \left( -\text{div}^*v - \frac{\delta}{2} |v|^2 \right) \, dx + \sup_{\varrho \in L_2(\partial_2\Omega)} \int_{\partial_2\Omega} \left( (y^* \cdot n) \varrho - \frac{\alpha}{2} |\varrho|^2 + g\varrho \right) \, ds \]
\[
\sup_{v \in L^2(\Omega)} \int_{\Omega} (-\text{div} y^* v - \frac{\delta}{2} |v|^2)dx = \int_{\Omega} \frac{1}{2\delta} |\text{div} y^*|^2 dx,
\]

\[
\sup_{\varrho \in L^2(\partial_2 \Omega)} \int_{\partial_2 \Omega} ((y^* \cdot n) \varrho - \frac{\alpha}{2} |\varrho|^2 + g \varrho)ds = \int_{\partial_2 \Omega} \frac{1}{2\alpha} |y^* \cdot n + g|^2 ds.
\]

Hence,

\[
F^*(\Lambda^* y^*) \leq \int_{\Omega} \frac{1}{2\delta} |\text{div} y^*|^2 dx + \int_{\partial_2 \Omega} \frac{1}{2\alpha} |y^* \cdot n + g|^2 ds.
\]
Now,

\[ F(v) = \int_{\Omega} \frac{\delta}{2} |v|^2 \, dx + \int_{\partial_2 \Omega} \left( \frac{\alpha}{2} |v|^2 - g v \right) \, ds , \]

\[ \langle \langle \Lambda^* y^*, v \rangle \rangle = \int_{\Omega} - \text{div} y^* v \, dx + \int_{\partial_2 \Omega} (y^* \cdot n) v \, ds , \]

\[ F^*(\Lambda^* y^*) \leq \int_{\Omega} \frac{1}{2\delta} |\text{div} y^*|^2 \, dx + \int_{\partial_2 \Omega} \frac{1}{2\alpha} |y^* \cdot n + g|^2 \, ds . \]

Therefore,

\[ F(v) + F^*(\Lambda^* y^*) - \langle \langle \Lambda^* y^*, v \rangle \rangle \leq \int_{\Omega} \frac{1}{2\delta} (\text{div} y^* + \delta v)^2 \, dx + \int_{\partial_2 \Omega} \left( \frac{\alpha}{2} |v|^2 + \frac{1}{2\alpha} |y^* \cdot n + g|^2 - (y^* \cdot n + g) v \right) \, ds . \]
We obtain

\[ F(v) + F^*(\Lambda^*y^*) - \langle \Lambda^*y^*, v \rangle \leq \int_{\Omega} \frac{1}{2\delta} (\text{div}y^* + \delta v)^2 \, dx + \int_{\partial_2 \Omega} \frac{1}{2\alpha} |y^* \cdot n + g - \alpha v|^2 \, ds. \]

\[ G(\Lambda v) + G^*(-y^*) + \langle y^*, \Lambda v \rangle = \int_{\Omega} \frac{1}{2} |\nabla v + y^*|^2 \, dx. \]

Two terms above give the error Majorant.
We observe that the Majorant vanishes if and only if
\[
\text{div} y^* + \delta v = 0 \quad \text{in} \; \Omega,
\]
\[
y^* \cdot n + g - \alpha v = 0 \quad \text{on} \; \partial_2 \Omega,
\]
\[
y^* = -\nabla v \quad \text{in} \; \Omega.
\]

These relations mean that
\[
-\Delta v + \delta v = 0 \quad \text{in} \; \Omega,
\]
\[
\frac{\partial v}{\partial n} + \alpha v = g \quad \text{on} \; \partial_2 \Omega,
\]

i.e., since \( v \) vanishes at \( \partial_1 \Omega \) it is but the exact solution.
